For town-dwellers, fruit and vegetables have always been available from shops, itinerant tradesmen, and markets. These outlets were supplied with produce grown in outlying commercial market gardens, many of which specialized in only one or two kinds of fruit or vegetable (asparagus, strawberries, mushrooms, or grapes, for example). From the late nineteenth century onward, produce markets depended increasingly on stuff imported from abroad, and it is this factor—plus the relative cheapness of bought food compared to the cost of growing one’s own—that has contributed to the demise of the great walled kitchen gardens. On the other hand, with the creation of the allotment system in the early nineteenth century, town-dwellers (ranging from wealthy tradesmen to artisans of the working class) were, and still are, enabled to raise a few fruits, flowers, and vegetables of their own on communal, rented plots provided either by philanthropists, speculators, or the municipality on the outskirts of towns. The original purpose of the allotment system was to offer a healthy pastime for heads of house-

holds who might otherwise squander their time and money in public houses and other dens of vice. Ten such gardens would occupy one acre and in 1835, according to William Howitt, in *Rural Life in England*, there were, on the outskirts of the English manufacturing town of Nottingham alone, “upwards of 5000 gardens, the bulk of which are occupied by the working class” (pp. 550–553).

Allotment gardens, traditionally equipped with little huts or summer houses, are still in use throughout Great Britain and Europe, providing their tenants, as they did in the past, with welcome retreats from the noise and dust of the city, as well as a healthy occupation and a supply of wholesome fresh food. Market gardens, with their vast glasshouses and forcing beds are not, for the purposes of this article, strictly kitchen gardens, although they supply similar produce, but the allotment garden is definitely in the kitchen garden category, being private and non-commercial.

Walled kitchen gardens invariably formed part of the gardens attached to any substantial country house. Unlike the other domestic kitchen gardens described above, these gardens were huge, occupying anything from one to twenty acres, commensurate in size with households often consisting of more servants than family, and capable of providing enough produce for feasts, balls, banquets, and numerous staying guests as well.

By the beginning of the twentieth century, kitchen gardens had reached the peak of perfection: the rarest and best of fruits, flowers, and vegetables were to be found here, raised by teams of highly skilled gardeners who used the latest in horticultural technology. This is not to say that the wealthier classes were alone in their love of luxury—plus a degree of natural curiosity and competitiveness—but peaches, melons, muscats, and pineapples cannot be raised in one’s own garden without considerable financial means.

These gardens supplied their masters with a succession of fruits and vegetables all year round, both delicacies and staples, and with ornamental plants and flowers for the house and for personal adornment. Indeed, the demise of these great gardens, which began after World War I, and was virtually complete by the end of World War II, is largely due to such fruits and vegetables being cheaply available to everyone in a supermarket. The modern shopper might be surprised to learn that from the late eighteenth century onward, glasshouses in these walled gardens were providing heat and shelter for tropical fruits and orchids as well as more temperate plants. Forcing beds ensured that there would be new potatoes, asparagus, and strawberries for Christmas and in early spring; mushrooms were grown in dark, heated sheds, to be available at all times; insulated and ventilated storage rooms kept grapes, apples, and pears in perfect condition over winter and into springtime. Common roots and vegetables such as onions, cabbages, and pumpkins were

likewise stored in specially constructed cellars and attics. Garden produce was even frozen, and kept in ice-houses. The kitchens made surpluses into pickles and preserves, and if the family was staying in town, fresh fruit, flowers, and vegetables—washed, trimmed, and packed in hampers—were sent up as required by the gardeners.

## Design

In layout, walled kitchen gardens show a marked similarity to one another; this is due to their being essentially working gardens, the design of which is led by function and has evolved through practice. Ideally they are rectangular, with the longest walls facing the sun; lean-to hothouses are ranged against the sunny side of the northernmost wall; sheds behind them (known as “back sheds”) house boilers or furnaces to heat the glasshouses, workrooms, storage rooms, and tool rooms, the men’s mess room, the head gardener’s office, his seed room, the mushroom house, and sometimes a *bothy* or hut for the unmarried gardeners. The head gardener is given a house for himself and his family, often built onto the walls themselves, and always as close as possible to the hothouses, so that he can keep a close watch on them and their contents. Forcing pits, frames, and hot beds occupy a separate yard beside or behind the back sheds, as does an enclosure for packing materials, poles and posts, fuel, composts, and manures. The “slip garden” (the area outside the main walls) was also cultivated, usually with the more robust vegetables or with soft fruits. The slip in front of the southernmost wall was sometimes used as an ornamental flower garden, especially if it was the garden through which visitors from the house might pass on their way to view the kitchen garden.

With the exception of glasshouses, which were not seen in kitchen gardens until the early eighteenth century, and then only rarely, the monastic, royal, and aristocratic gardens of medieval Europe were very similar; they were modeled on treatises written by classical authorities such as Pliny, Cato, Varro, and Columella. Situated conveniently close to the back kitchens and the stables or home farm (which provided dung), stoutly defended by walls of mud, brick, or stone (depending on the locality), they were laid out if possible on land sloping toward the sun, on a four-square grid, with long, narrow raised beds.

The layout of the beds and paths was dictated by a watering system in which the paths between the beds acted as channels, the water coming either from central ponds, reservoirs beyond the garden, or wells, tanks, and cisterns within it. It was distributed in water carts, or by pumps and water wheels. The invention of the hydraulic ram in the mid-nineteenth century allowed gardens to be made on higher ground than would have been possible before. The invention of the horse-drawn seed drill in the late seventeenth century, whereby seed was sown in rows on flat ground, was taken up at first by farmers and then by market gardeners, effectively doing away with

raised beds in the larger gardens of the more northern parts of Europe.

## Diversity of Plants

The variety of plants grown in the earliest kitchen gardens was dependent on locality; those known to thrive in the wild were taken in and “improved” by selective breeding, fertile soil, shelter, and abundant watering. Travelers, merchants, nurserymen, and itinerant seedsmen introduced novelties from further afield. With the voyages of discovery made by Europeans from the fifteenth century onward, plants from across the world were brought into Spain, Portugal, France, Italy, the Netherlands, and Britain. They were taken to the gardens of botanists and apothecaries, as well as the kitchen and flower gardens of enthusiasts, to be assessed as much for their economic or medicinal values as for their edibility or beauty.

These introductions were challenging to the gardener. Many of them needed protection over winter and heat in order to survive. The hot bed, a flat-topped mound of warm, fermenting horse dung covered by a bed of rich, sifted soil and surmounted by a protective frame, was introduced to Moorish Spain by the Arabs in the eleventh century, but was not used in the rest of Europe until four centuries later, when it was used for raising the seedlings of exotics, melons, cucumbers and out-of-season salads. Orangeries (also known as conservatories or greenhouses) were used for conserving citrus fruits and other exotic greens. Originally a dark, well-insulated overwintering shed, the orangery gradually evolved into a high-windowed ornamental building, with heat provided by small smoky stoves. Dutch gardeners led the way in seventeenth-century stove and glasshouse development. They made their orangeries lighter by giving them sloping glass fronts; they improved ventilation and perfected a system of underfloor heating by means of hot-air flues heated by small furnaces at the back of the house. With the discovery toward the end of the seventeenth century of how to raise pineapples, they introduced the use of hot beds heated by fermenting tan bark, in place of horse dung.

By the 1720s, British gardeners had overtaken the Dutch in horticultural invention. Gripped by a mania for growing pineapples, they developed glazed, heated pits and glasshouses expressly for that fruit, eventually adapting the system to suit vines, peaches, and tropical plants. With the industrial revolution, which began in Britain, came the invention of the steam boiler and later the hot water boiler, as well as the glassworks and foundries for the manufacture of iron-framed glasshouses in which to raise these plants, and a new, industrial wealthy middle class to enjoy them.

Even before the sixteenth century, Flemish and French gardeners were masters in the cultivation of fruit. They raised innumerable varieties of hardy fruits such as plums, apples, pears, and cherries, as well as figs, grapes,

and the more tender, early-flowering apricots, almonds, peaches, and nectarines. They were experts in grafting and in training trees to grow as fans, espaliers, cordons, and free-standing dwarfs. With the arrival in Britain of the Dutch King William III, in 1688, this style of fruit growing became fashionable in British gardens where, until then, fruit growing had been concentrated mostly on hardy orchard fruits. As on the Continent, dwarf fruit trees, pruned to form decorative balls, goblets, spindles or pyramids, were used ornamentally in beds lining the kitchen garden paths, or were even given a *jardin clos*, an enclosed fruit garden of their own. Fruit trees with branches trained as horizontal bars (*espaliers*), as single, double, or treble stems, either upright, oblique, or horizontal (*cordons*), or as branches trained into a flat palm or fan shape (*fans*) needed the support of free-standing trellises or high walls. Walls were especially needed too, to accommodate the more tender wall-fruits.

### An Industrial Quality

Thus the walls surrounding the kitchen gardens of northern Europe and Great Britain increased both in height and extent. Gardens of more than four acres were divided and subdivided by yet more walls, some of which were heated by horizontal, serpentine flues running from small fireplaces situated at the back.

High garden walls were beneficial to wall-fruits, created a benign, sheltering microclimate within the garden, provided support for taller, more extensive glasshouses and back sheds, and hid the whole process of growing kitchen produce from sight, giving the place a secretive air. It should be noted, though, that this complex was the headquarters of the gardens as a whole; it was where the entire workforce assembled and received orders, where the garden boys were educated by the head gardener, where equipment was kept, and all the choicest plants raised and nurtured.

It was also becoming increasingly industrial. For a visitor to an early-nineteenth-century kitchen garden, as described by Jane Austen in *Northanger Abbey*: "The walls seemed countless in number, endless in length; a village of hot-houses seemed to arise among them, and a whole parish to be at work within the inclosure." She does not mention the numerous smoking chimneys perched above hot walls and glass houses—or how, on a windy day, strawy dung from frames, pits, and hot beds would be blowing about and there would be a noticeable smell of rotting cabbage leaves, celery, onions, and leeks. These aspects, and even the very sight of "a whole parish" going to and fro with their barrows and carts, were less pleasing to eighteenth- and nineteenth-century gentlefolk.

### The Landscape Movement

Apart from the sensibilities of its owners, the landscape movement was to some extent responsible for the removal of the kitchen garden with its high walls to some distance from the house. If it could still be seen, it was screened

by beds of tall, ornamental shrubs or, if the screen was to act as a shelter belt as well, by tall forest trees. "If from your best room windows any objects should intercept your sight," wrote landscape designer J. Trusler in his *Elements of Modern Gardening* (1784), "go to the top of the house and from thence select the best distance and background, preserving in the piece such of the buildings and plantations as will suit the composition. . . ." Not everyone agreed; the political reformer William Cobbett, in his *English Gardener* thought it "the most miserable taste to seek to poke away the kitchen garden, in order to get it out of sight" (p. 8).

At the beginning of the twenty-first century, these arguments seem trivial, for the gardens are in ruins, with little but the walls to be seen. But there is some hope for their revival. Local communities see them as sources of fresh, organic produce; others will use them as living museums in which to teach old horticultural skills, and display long-forgotten fruits and vegetables.

**GASTRONOMY.** Most dictionaries define gastronomy as “the art and science of good eating,” or “the art and science of fine eating.” The etymology of the word is generally attributed to the title of a poem by French attorney Joseph Berchoux, “Gastronomie” (1801). Early descriptive writings often assume gluttony. One versed in gastronomy is said to be a gastronome, while a gastronomist is one who unites theory with practice and thus becomes a gourmand (gourmet).

The original suffix root of gastronomy derives from the Greek word *nomos*, meaning ‘laws that govern’, which led to the notion that gastronomes are those who only

dwell upon classic and haute cuisine. Implied too is that “the art and science of good eating” is confined to expensive, lavish, and complex meals requiring equally expensive silver and china. Fortunately, as is the case with so many rules and regulations, such rigidity of form can become uncomfortable. One so-called early proponent of gastronomy asserted that a true gastronomist should shun diversity—a rather narrow footnote by today’s understanding.

Gastronomy has evolved from its original dictionary meaning to the point that it really would be best studied broken down into subsets by culture.

A further denotation of *nomos*, ‘the sum of knowledge of a specific subject’, gives gastronomy a meaning that includes a person’s command of the totality of knowledge regarding the art and science of good food and eating. Rather than just beautifying the ritual of consumption, gastronomy now entails an appreciation and understanding of the many avenues of cooking and food production. For example, today’s gastronomist would do well to have some knowledge regarding food chemistry and physics, food history, foodways, and culinary anthropology, including a link to the many cultures of the world via computer technology.

One should seek a better understanding of agriculture, aquaculture, and the technology of newer cooking

methods and equipment, as well as information on the impact of eating and diet upon health, including food-borne disease and worldwide ecology. Gastronomy should promote lessons on how to taste, savor, and fully sensualize the dining experience, whether it is a family meal at home or a special dining-out event.

Simpler repasts should be enraptured alongside the grandest banquets. Standing at a seaside fish market and savoring a freshly shucked oyster just harvested and chilled from the sea can be savored as much as the expensive three-hour feast served in a banquet hall.

There is a tendency to judge food and cooking solely by what it looks like. When dining out, taste and aroma are demoted in favor of stylistic architecture. People, especially Americans, are losing the ability and sensibility of how to taste. Americans no longer savor or appreciate the joy and satisfaction of eating. Entertaining and pleasant conversations over dinner seem to have disappeared; food fads come and go before ever having had a chance to even establish an identity. It is time to relearn or reemphasize how the senses can be used to fully appreciate and relish the hedonistic pleasures of life. People are equipped with the necessary anatomy and physiology to elevate a boring biological function to one of life's greatest pleasures.

**GELATIN.** Gelatin (also gelatine, jelly in Britain, jelly powder in Canada, and *gelée* in France) is a flavorless, transparent thickener derived from animal collagen that dissolves when heated and congeals when cooled, allowing foods to set. This versatile ingredient provides

unique textural and sensory properties to both savory and sweet foodstuffs such as mousses, gummy bears, Turkish Delight, nougat, jellied soups, Bavarian cream, aspic, and Jell-O.

Gelatin is composed of protein molecules, made up of chains of amino acids. When placed in liquid, the molecules swell and then dissolve, and the chains separate. After cooling, they re-form as tightly as before. In the warmth of the mouth, they melt, providing excellent flavor release. This property and gelatin's easy digestibility and absorption by the body makes gelled desserts appropriate for children, invalids, and the elderly.

Nutritional value of gelatin was recognized as early as the Napoleonic Wars (1800–1815) when the French used it as a source of protein during the English blockade. Commercial gelatin contains no fat or cholesterol and few calories, making it popular with people who have diet and heart concerns. Commercial manufacturers claim that gelatin promotes nail and hair growth, as well as flexible joints and healthy bones. However, the protein in gelatin is missing an amino acid and thus is not absorbed as a complete protein by the body.

#### Making Gelatin

The discovery of gelatin was probably serendipitous: When animal bones and hides are boiled in water, the broth that results will set upon cooling. From the Middle Ages through the eighteenth century, making gelatin was a daylong, laborious process in which cattle hooves were boiled for six hours. The stock was clarified as it dripped through a jelly bag, boiled again, and then allowed to sit. Not surprisingly, production was limited to wealthy households with many servants. Another early

Copper molds for gelatin became extremely ornate in the nineteenth century. Different colors of gelatin, as well as different flavors, were often layered together in molds to create elaborate patterns for the table. Copper molds from England, circa 1870. ## JELL-O

Part of the early success of Jell-O was its strong marketing appeal to children. This 1908 Jell-O brochure shows two disappointed children who have just been served baked apples instead of the Jell-O they expected. ROUGHWOOD COLLECTION.

source of gelatin in the Middle Ages was hartshorn (antlers of the hart deer).

Today, the substance is manufactured commercially all over the world. In the United States most gelatin is derived from pig skin. Strictly speaking, this is not a kosher practice (although interpretations vary), and it is not permissible under Islamic dietary law. An alternative, isinglass (made from the air bladders of sturgeon), is acceptable to the religious and vegetarians. Another alternative is agar, made from a variety of red seaweed, commonly used in Japan where it is known as *kanten* and used in the manufacture of ice cream. Cattle form the basis of gelatin in France and Britain, raising safety concerns about transmission of mad cow disease even in the United States where some gelatin is imported from Europe.

Commercially manufactured gelatin is packaged in ¼-ounce envelopes of desiccated granules; paper-thin sheets, known as leaves (used in jelled Central and Eastern European desserts and aspics); and meltable blocks (Great Britain). In Latin America, gelatin is often mixed with milk or cream instead of water for the popular creamy desserts. In Russia, gelatin encases pigs' feet and other meats.

Aside from home and restaurant cooking, gelatin has wide application in the food industry where its functional properties are used to gel, thicken, stabilize, emulsify, bind, film, foam and whip prepared foods. Among other items, gelatin is incorporated into marshmallows, cake

Jell-O has become a cultural icon in the United States. Invented by Pearle Bixby Wait in 1897, (the name Jell-O was coined by his wife, May), this flavored gelatin's longevity is credited to its convenience for dessert, its popularity, especially with children, and its ability to inspire smiles, jokes, and playfulness. Beginning with strawberry, raspberry, orange, and lemon, Jell-O in the early twenty-first century comes in twenty-three flavors, including white sparkling grape, watermelon, and passion fruit. Strawberry is the best seller. Over a million boxes are sold every day; Salt Lake City, Utah, is the number-one consumer city.

Aside from thousands of inventive serving ideas (including one from 1930 for forcing set Jell-O through a potato ricer), Jell-O has spawned collectors (of original boxes, early advertising, recipe booklets, molds, glasses); Jell-O shots (alcoholic treats made by mixing in liquor); Jell-O wrestling (sometimes in the nude in large vats); the Jell-O Museum in Le Roy, N.Y.; an attempt to measure the brain waves of Jell-O; and countless websites.

Not everyone thinks Jell-O is benign. During the 1950s, when femininity was defined as docility, complicated molded constructions with fruits precisely placed according to pattern were popular, raising questions about a foodstuff that controls and keeps things in their place. One researcher claims that the marketing of Jell-O depicts women as inept homemakers. It is hard not to wonder about the larger social message of "perfection salad," a prescribed concoction of cabbage, celery, and red peppers in tomato Jell-O, popular at the turn of the twentieth century. Such prescription becomes a symbol of conformity and stifles creativity.

mixes, frostings, bakery glazes, meringues, ice cream, coffee, and powdered milk.

### Medieval Beginnings

Elaborate molded jellies began to grace aristocratic British banquet tables in the fourteenth century. In the Late Medieval period (the 1400s) through the 1500s, cooks made savory and sweet jellied dishes using meat, chopped fine, mixed with cream or almond milk that was flavored with spices, rosewater, or sugar to fashion creations known as cullis, gellys, or brawn. In 1754, the first English patent for the manufacture of gelatin was granted. During the Victorian era, copper, and later aluminum, molds were introduced, which made possible the presentation of tall, shimmering creations. Unflavored

dried gelatin became available in 1842 from the J and G Company of Edinburgh, Scotland.

Gelatin had an esteemed role in classic French cuisine. Escoffier's legendary *Guide Culinaire* (1903) includes a chapter on aspic jellies (savory gels) in which the great chef named two kinds: one flavored with champagne; the other with sherry, Marsala, or Madeira. Surprisingly, he mused that aspics might be even more important than stock, the bastion of Gallic cooking, because a cold meat, poultry, or fish entree (known as *chaud-froid*) is nothing without its glimmering coating of aspic. He warned that the value of the aspic decreased in direct proportion to its increasing firmness. The ideal was a softer consistency so aspic could even be served in a sauceboat. Gelatin also figured in many classic French desserts like blanc-mange, charlottes, mousses, and Bavarian creams.

### Gelatin in the United States

In America, in 1845, Peter Cooper, inventor of the steam locomotive, secured a patent for a gelatin dessert powder called Portable Gelatin, requiring only the addition of hot water. The same year, the J and G Company began exporting its Cox Gelatin to the United States. The new formulas never gained much popularity, however, and as late as 1879 when the classic *Housekeeping in Old Virginia* was published, editor Marion Cabell Tyrer, while admitting that jelly made of calves and hogs was "more troublesome," claimed it was more nutritious than Cox's or Nelson's desiccated formulas. Plymouth Rock Gelatin Company of Boston patented its Phosphated Gelatin in 1889. In 1894, Charles Knox introduced granulated gelatin, making the brand something of a household word. This opened the way for a plethora of American recipes that gained popularity, particularly during the 1950s when chiffon pie and tomato aspic (made of gelatin and tomato juice) became staples.

Although Jell-O is considered *déclassé* in upscale restaurants, gelatin was resurrected and frenchified by American chefs in the late 1990s, who reverted to calling the sweets "gelées." These creative formulas have been limited only by imagination since virtually any liquid can be used—coffee, champagne, grape and beet juice, rosé wine, sangria, and fruit poaching liquids. What began in the Middle Ages as an elite food has come full circle and returned to gourmet status.

**GENDER AND FOOD.** Across many cultures and epochs, people have constituted, expressed, and bridged gender differences through foodways—the beliefs and behaviors surrounding the production, distribution, and consumption of food. Through the division of labor, alimentary exchanges, access to food, and the meanings surrounding eating, men and women have enacted their identity, roles, and power.

### Gender and Food Production

In many cultures, men and women define their economic relationships in food-centered productive roles. In hunting-gathering and pre-industrial farming cultures, men and women share in food production but have distinct roles. Among the !Kung of the Kalahari Desert, for example, women gather vegetable foods and men hunt animals. Although women produce the great majority of the food, men produce highly desired meat, and thus the contributions of both sexes are relatively equally valued, which contributes to the gender egalitarianism that is a hallmark of the !Kung. In Wamira, Papua New Guinea, men and women contribute to growing taro at different stages in the agricultural cycle: men prepare the soil and plant the tubers; women weed the gardens and tend the growing plants; men harvest the mature tubers (Kahn, 1986). They promote gender interdependence and mutual respect by symbolically linking their complementary roles in the production of taro to those in the reproduction of children. Among share-cropping peasants in Tuscany in the first half of the twentieth century, men focused on producing grain, grapes, and olives, while women took care of the family vegetable garden and the courtyard animals. Women also helped harvest the major crops, gathered wild foods, and preserved and prepared key comestibles. Because women's productive work was associated closely with their taken-for-granted reproductive roles in the home, it was less highly valued than men's contributions to food production.

Around the globe, women predominate in the lowest status, lowest paying, and most servile roles in agribusiness and the food industry as fieldworkers, waitresses, fast-food servers, and cannery and meatpacking workers. In rural Iowa, for example, women were almost completely excluded from the pork-packing industry when jobs were unionized and pay was good. They entered the industry in increasing numbers in the 1980s,

The tension between male and female views of food and cookery is satirized in this picture of the helpless husband and the amused wife. © H. ARMSTRONG ROBERTS/CORBIS.

when wages were falling, and at the end of the twentieth century they were still almost always relegated to the poorest paying packing and cleaning jobs in the plant rather than the better-paying cut and kill jobs (Fink, 1998).

Women are almost universally in charge of cooking and feeding, starting with breast-feeding the newborn. Through breast-feeding, women forge deep bonds with children and give them the best possible food, yet across the globe, breast-feeding has declined under the flood of commercial formulas. While formula has been beneficial to some women who cannot or do not want to breast-feed, it lacks the many benefits of breast milk and has contributed to the disempowerment of mothers who have lost confidence in their bodies and control of their children's food (Blum, 1999; Van Esterik, 1989; Whitaker, 2000).

Women's labor to produce, preserve, prepare, serve, and clean up food sometimes brings recognition and value, as among Ecuadorian peasants. But often women's food roles are devalued, especially under conditions of capitalist economic development, as in late-twentieth-century central Italy, where women's food roles became isolated in the home and separated from valued, public production. Florentine women struggle to balance their

desire to work outside the home with traditional expectations that they prepare elaborate meals for both lunch and supper. They suffer conflicts that men, free from culinary expectations, do not face. As in Italy, in England and the United States women's food roles in the home are sometimes problematic because they are "naturally" assigned to women and the labor involved is both underestimated and undervalued. Women are obligated by custom and culture to cook and please their husbands while subordinating their own desires (Charles and Kerr, 1988; DeVault, 1991). In lesbian and gay households, feeding work is undervalued and confers low status, so many couples tend to minimize its significance and the implicit subordination of the partner who does it (Carington, 1999).

### Gender and Food Consumption

Food consumption signifies gender and sexuality in diverse cultures. Eating often stands for intercourse, foods for sexual parts. Among the Wamira, taro represents male virility, and the size and fullness of the tubers stand for the potency of their producer. Male and female identities are expressed through association with foods and rules about consumption. The Hua of Papua New Guinea classify foods into two main categories: *koroko*, or female foods, are wet, cold, fertile, soft, and fast growing; *haker'a*, or male foods, are dry, hot, infertile, hard, and slow growing. Hua men and women believe they can gain some of each other's powers and attenuate gender differences by eating each other's foods (Meigs, 1984). In other cultures, however, rules about food consumption promote hierarchical conceptions of gender. In nineteenth-century American bourgeois homes, women were discouraged from eating meat, which was believed to stimulate excessive sexual appetite. Late-twentieth-century U.S. college students still believed that men should eat lots of meat and women should eat lighter foods, such as salads. They valued hearty appetite and big bodies in men, but preferred dainty eating and small bodies in women, thereby forcing women to deny their appetites and reduce themselves (Brumberg, 1988).

In Western cultures for at least seven centuries, women have much more commonly than men practiced extreme fasting and compulsive eating to communicate unspoken longings for autonomy, control, and power. A significant number of medieval women used food refusal and miraculous emissions of breast milk as expressions of piety and spiritual power. Middle-class nineteenth-century American girls refused food to demand attention and speak their needs for full personhood. Many U.S. girls at the turn of the twenty-first century struggle for control by pursuing excessive thinness through extreme fasting or bingeing and purging, while others eat compulsively to numb the pain of abuse. Yet women from many cultures have forged positive relationships with their bodies that allow different and more ample forms of body beauty. In cultures as disparate as Fiji and Flo-

## MALE COOKS IN THE MID-TWENTIETH CENTURY

Insights into the gender-based division of labor in American culture are beautifully illustrated by cookbooks that were written by men for other men in the first half of the twentieth century. Among other things, they illustrate that, just like women, men had to deal with the consequences of being fettered by other people's notions of what was a permissible interest or occupation. Men were expected to do important, well-paying work, and if they happened to be interested in cooking, they were expected to be executive chefs. Men who wrote cookbooks could write without embarrassment about the pursuit and preparation of wild game, perhaps, or the perils of outdoor barbecuing, but everyday home cooking was understood to be women's work.

Nevertheless, men interested in writing recipes for home cooks managed to do so without losing their self-respect, but in order to pull it off they had to set themselves apart from women. Authors had to prove that male cooks were more creative and inspired than women, who were understood to be more concerned with the mundane task of getting three meals a day on the table. Male cooks had to convince themselves and others that, unlike women, their approach to food was spirited and adventurous, not weighted down by frets over level measurements or undue concerns about nutrition. The concern of the male cook, of course, was to appear masculine enough not to be mistaken for a sissy or the least bit effeminate; he would prove his legitimacy by establishing his superiority over women.

Certain American foods have been linked either to men or to women, creating stereotypes that designate light, sweet foods such as jams, jellies, and cupcakes as female, while male food is heavy and spicy, with the only acceptable vegetable being potatoes.

Male gourmets were happy to see the prohibition of alcohol lifted in 1933 so that they could occupy themselves with matching good food to good wines. Seeking like-minded companions, they formed societies to share their interest in fine food. J. George Frederick, founder and first president of the New York Gourmet Society, established his leadership by creating "A Gourmet's Code of Modern Dining," published in his book, *Cooking as Men Like It* (1939).

Frederick has clear ideas about differences between men and women in their approaches to food. While he credits women with having made some striking advances in their cooking, he finds them too occupied with cleanliness, purity, and nutrition, rather than what is "savory and tasteful" or "varied and succulent," the priorities of men.

While old ways of thinking tend to persist, new styles of eating would suggest that at the start of the twenty-first century, men who like to cook and bake can do so without feeling their manhood challenged, and women who have no interest in domesticity will perhaps no longer be considered unnatural.

*Barbara Haber*

rence, people decry thinness as evidence of social neglect and celebrate women's plumpness as a reflection of well-being and fertility.

### Gender and Food Distribution

In food exchanges, men and women create meaningful relationships and demonstrate wealth and power. In many agricultural and hunting-gathering societies, men give away food to acquire and demonstrate political leadership. In Wamira, Papua New Guinea, men gain allies and shame enemies through massive food feasts. Women in many cultures exercise influence over family members by giving or withholding food, and they contribute to establishing hierarchy in the family by allocation of delicacies. When serving the soup, Ecuadorian Indian peasant women show favor by distribution of the prized chunks of meat, and they express ire at husbands by failing to prepare dinner, a grave insult and social transgression

(Weismantel, 1988). In many cultures, women and men initiate relationships by eating together—whether as a date among Western college students or as a marriage proclamation by sharing yams among the Trobriand Islanders. Feasts celebrate community and gender cooperation across all cultures. For example, in Tresnuraghes, Sardinia, for the feast of Saint Mark, shepherds donate sheep, which their wives cook and distribute—solidifying community, demonstrating wealth, and sharing food widely.

In many cultures, gender hierarchy is expressed through access to food. Often women have less access to food than men, a practice supported by their economic dependence, by beliefs that they need less, and by pregnancy food taboos. The Mbum Kpau, for example, prohibit women from eating chicken or goat lest they die in childbirth or suffer sterility, a major tragedy because of the importance of childbearing to these women. While

in practice the prohibitions have little effect on daily consumption, they reinforce men's power by emphasizing their right to meat and other preferred foods (O'Laughlin, 1974). Under conditions of food deficiency, women are particularly vulnerable to hunger, along with children and the elderly, because they generally have less power over food and other resources than men. In Malawi, under normal conditions, women controlled grain stores and lived close to their relatives in matrilineal and matrilocal households. But in the 1949 famine, crops failed and women had no grain to control. Wage labor, exclusively practiced by men, was the only way to gain access to food, but many men left their wives' households to search for food in the villages where they were born, so women lost access to men's labor and wages while still being responsible for feeding children, the elderly, and themselves (Vaughn, 1987). Under conditions of food insecurity, male power over food is particularly salient, but even under conditions of food security, gender relations play an important role in food production, distribution, and consumption across cultures and time periods.

**GENE EXPRESSION, NUTRIENT REGULATION OF.** The human genome (or genetic material) is comprised of deoxyribonucleic acid (DNA) that encodes information required for all life processes, including growth, development, reproduction, and even cell death. The functional units within the genome are called genes. Genes are hereditary regions of DNA that encode functional molecules, either proteins or ribonucleic acid (RNA) species. The human genome encodes approximately 100,000 genes on 23 chromosomes. DNA resides in a specific compartment within the cell, known as the nucleus. Each nucleated human cell within an individual, regardless of its origin, contains identical DNA. However, the genetic code is expressed or read differently in each cell type. Gene expression refers to the processes in which the genetic code is deciphered to produce a functional macromolecule, either protein or RNA. While some genes are expressed in all cells, others are expressed exclusively in certain tissues or organs. This selective reading of the code imparts very different chemical, functional, and morphological properties to each cell type and ultimately defines the function of a tissue or organ. Genes

can also display temporal specific expression. For example, some genes are expressed only in the fetus, while other genes are not expressed until puberty or adulthood. Therefore, human DNA not only contains all of the genes required to assemble a human organism, but also encodes information that directs where, when, and how much an individual gene will be expressed.

### Mechanisms of Gene Expression

Genes encode proteins. Proteins are polymers of amino acid building blocks that serve a variety of biological functions. Proteins can function as intracellular scaffolds that maintain cell integrity; others are transporters that permit specific nutrients and other small molecules to enter the cell. Proteins also can be enzymes that catalyze the many chemical reactions required for cell survival. While DNA is present in the nucleus, protein synthesis occurs in the cytoplasm, a separate compartment within the cell. Therefore, an intermediate molecule is needed to transfer the genetic information from the nuclear compartment that contains the code to the cytoplasmic compartment where the code is read. This intermediate molecule is termed “messenger RNA,” and it is a short-lived functional copy of the genetic code. The process by which the genetic code, DNA, is copied to make a messenger RNA molecule occurs in the nucleus and is termed “transcription.” The process of reading the genetic code from a messenger RNA molecule occurs in the cytoplasm and is termed “translation.” The end product of translation is a protein molecule.

The expression of some genes is predetermined and cannot be altered. However, the expression of other genes, particularly those involved in nutrient storage, processing, and metabolism, is dynamic, and can be influenced by the cell’s environment. Therefore, in some instances, gene expression can be an adaptive process. It is now well established that the expression of many genes is, in part, constrained by the nutrient environment—giving credence to the old adage, “you are what you eat.” There are more than forty nutrients that are essential for mammals, and deficiencies in any of these nutrients have direct impacts on health. The cellular demand for these nutrients can vary as a function of growth, development, age, reproductive status, and immunity. However, for many organisms, the availability of nutrients can vary daily, weekly, and, in some cases, seasonally without notable changes in health. This is because organisms adapt to nutrient supply by altering gene expression. This alteration, in turn, enables cells to increase their storage capacity for certain nutrients, alter the absorption or excretion of certain nutrients, use alternative metabolic pathways, or reprogram metabolic pathways.

### Nutrients as Informational Molecules

If organisms have evolved the ability to reprogram themselves for optimal utilization of the available nutrient resources, then the implication is that a nutrient is not merely

### FAMILIAL HYPERCHOLESTEROLEMIA

Familial hypercholesterolemia is a disease that results from genetic mutations in the low-density lipoprotein (LDL) receptor. It is one of the most common inborn errors of metabolism. Individuals with one mutated copy of the gene (referred to as heterozygotes for this mutation) number about one in five hundred, whereas one in a million individuals carry two mutated copies of this gene (referred to as homozygotes for a mutation). LDL receptors are necessary for transporting LDL into cells from serum. LDL is a major cholesterol transport lipoprotein in human plasma, and individuals with LDL receptor mutations accumulate LDL in serum because LDL transport into cells is impaired. Plasma cholesterol levels from affected heterozygotes range from 350 to 550 mg/dl, and these values can exceed 1000 mg/dl for affected homozygotes. Individuals with elevated serum cholesterol have a high risk for developing heart disease at very young ages.

Cholesterol is an important component of cell membranes, and it serves to decrease their fluidity. Mammals can synthesize cholesterol in the absence of sufficient dietary cholesterol, but the endogenous biosynthesis is tightly regulated and inhibited by dietary cholesterol supply. A transcription factor known as SREBP (Sterol Response Element Binding Protein) regulates the expression of a gene that encodes a key enzyme that is necessary for cholesterol biosynthesis. When dietary intake of cholesterol is adequate, this transcription factor is sequestered in the membranes of the Golgi compartment of the cell and is inactive. When cellular cholesterol levels fall, however, the membranes in the Golgi become more fluid. This results in the liberation of SREBP from the membrane and enables it to travel to the nucleus, where it can activate the expression of genes that are necessary for cholesterol biosynthesis. Through this regulation, cholesterol biosynthesis occurs only when dietary sources are limited. However, this mechanism of gene regulation fails in familial hypercholesterolemia. Because LDL cholesterol is not effectively transported into cells, the cells cannot sense extracellular cholesterol levels, and therefore cellular SREBP activity and cholesterol biosynthesis is constantly activated. Activated cholesterol biosynthesis serves to further increase serum LDL concentrations in affected individuals.

a chemical component required for a particular metabolic function, but also that it plays an informational or signaling role in the cell. As with any system that transmits

information, the signal must have a sensor or receiver that can accept, decode, and relay the information that has been transmitted. Cellular proteins that receive and transmit this information are termed “receptors.” The receptors then must relay this information via a transducing mechanism to the part of the cell that is capable of reprogramming the cell to adapt to the new environmental conditions. This reprogramming can occur in the cell nucleus or cytoplasm. It can involve changes in the expression of genes (transcription and translation), the stability of messenger RNA and protein, or the activity of proteins. The key principle behind nutrient control of gene expression is specificity. Each receptor must have the capability of binding a nutrient-signaling molecule with specificity and should initiate an adaptive change.

### Nutrient Control of RNA Synthesis

The best-understood signaling molecules are hormones such as estrogen and testosterone. A hormone is produced by a particular tissue and causes a specific biological change in the same tissue or a different tissue located elsewhere in the body. In some cases, these molecules can enter a cell and bind to a particular protein molecule, termed a “nuclear receptor.” The receptor-hormone complex then travels to the nucleus, binds very specific regions of the DNA, and turns on the expression of genes not normally expressed in the absence of the hormone. This change in gene expression imparts new functional roles to individual cells, which can impact the entire organism greatly. In this manner, diverse biological processes can be initiated, including puberty or menstruation. Certain nutrients can also influence gene expression in a similar manner. Nutrients, including

vitamin A, vitamin D, and certain fatty acids, bind nuclear receptors and influence the expression of genes. These nutrient receptors enable cells to sense their nutrient environment and adjust cellular metabolism accordingly by altering the expression of genes.

### Nutrient Control of Protein Synthesis

Nuclear receptors are effective in reprogramming DNA transcription to adapt to nutrient environments. Other mechanisms exist to alter gene expression without changing rates of DNA transcription. In fact, alteration of translation is a common mechanism that permits cells to adapt rapidly to changing nutrient environments. Iron is the paradigm for nutrient regulation of gene expression at the level of translation. Iron is a critical component of many metabolic proteins and enzymes involved in oxygen transport, energy metabolism, and DNA synthesis. Iron deficiency results in several disease states, including anemia. Therefore, the body must retain sufficient iron stores to stave off such pathologies. However, iron is also a potent oxidant and, if not bound by proteins in the cell, it can destroy DNA and proteins, and catalyze events that initiate cancer. Therefore, the body must store iron, but in such a manner that prevents the iron from destroying the integrity of its cells. Cells are protected from the deleterious effects of iron by sequestering it in a protein shell called ferritin. Cellular iron is stored in ferritin until required. Ferritin synthesis is rapidly induced when cells are exposed to iron and this increased synthesis is directly regulated by iron. Cells contain an iron-sensing protein called the iron regulatory protein (IRP). This protein binds either iron or ferritin messenger RNA but cannot bind both molecules simultaneously. When iron is not available to the cell, the intracellular concentration of nonprotein-bound iron is very low and IRP does not contain bound iron. This results in IRP being available to bind ferritin messenger RNA, which stops new ferritin synthesis. However, when cells are exposed to iron, IRP contains a bound iron molecule and cannot bind ferritin messenger RNA, and ferritin synthesis occurs. In this manner, the iron storage protein ferritin is only synthesized when it is required to store new iron.

### Permanent Adaptation to Nutrient Supply

There is accumulating evidence that prenatal and postnatal nutrition can permanently alter cellular metabolism by altering gene expression throughout adulthood, a phenomenon termed “metabolic imprinting.” Low birth weight, which occurred in infants born to survivors of the Dutch Famine of 1944–1945, has been linked to an increased risk of chronic disease later in life, including adult obesity, insulin resistance, hypertension, and cardiovascular disease. The susceptibility to these disease states is influenced both by dietary habits as well as one’s genetic predisposition or heritage. Although the biological basis for metabolic imprinting is not yet proven, the suggestion that gene expression can be programmed by fetal and postnatal nutrient environment has far-reaching im-

plications. For many adult chronic disease states, dietary management is an important component of the therapy. If metabolic imprinting occurs, dietary management early in life may also be advantageous in preventing numerous chronic disease states that do not surface until adulthood.

### **Nutritional Modulation of Gene Expression in Health and Disease**

The relationships between nutrient availability and adaptive changes in gene expression are critical to understanding the role of nutrition in health and disease. For many nutrients, either dietary insufficiency or excess can result in or contribute to disease onset. Nutrient modulation of gene expression serves to protect the cell from the deleterious effects of both under-nutrition and over-nutrition. Hereditary hyperferritinemia-cataract syndrome is a human disorder associated with altered regulation of iron homeostasis. Affected individuals have mutations in a ferritin gene that result in the synthesis of a ferritin messenger RNA that encodes a normal functional ferritin protein, but the mutation does not permit IRP to bind to the messenger RNA and stop translation. Therefore, these individuals can no longer regulate ferritin levels in response to changes in iron intake. As a result of this mutation, these individuals contract early-onset bilateral cataract associated with a progressive decrease in visual acuity. Ongoing research is identifying many other nutrient-related disease states that result from dysregulation of nutrient control of gene expression.

**GENETIC ENGINEERING.** Genetic engineering involves the directed alteration of an organism's DNA (deoxyribonucleic acid)—that is, its genetic material. This technology has been applied to microbes, plants, and animals, and consequently used to modify foods, animal feedstuffs, and food-processing reagents.

Domestication and improvement of plants and animals for agriculture initially relied on identification of individuals with desirable characteristics from among natural populations. Applying knowledge of genetics to the breeding of plants and animals resulted in more rapid progress and remains vitally important to agricultural development. Traditional breeding, however, is constrained by the boundaries of sexual compatibility, which limits the choice of parents that can be used as sources of genes and traits to improve a specific crop or animal to those that can produce progeny through sexual reproduction. Genetic engineering expands the source of genes that can be used to modify the characteristics of plants and animals.

### **Technology of Genetic Engineering**

Genetic engineering requires three fundamental technologies: the ability to isolate and modify the DNA of specific individual genes; an understanding of the mechanisms that regulate how genes function and how these can be manipulated; and the capacity to transfer genes into an organism. These have all been developed following the discovery of the structure of DNA in 1953. Genetic engineering of microbes was first reported in 1973, followed in the next decade by similar achievements in plants and animals. Because DNA is the genetic material in all organisms, genes for genetic engineering can be taken from any source, or even synthesized. Modification of genes may be necessary, particularly in regions that control how they operate, in order for the genes to function effectively in the recipient organism. *Agrobacterium tumefaciens*, a bacterium that transfers DNA into plant cells as part of its normal life cycle, is used commonly to transfer genes into plants, although other methods such as the "gene gun" also have been developed. Genetically engineered plants are technically "transgenic organisms," as they contain transferred genes. However, they are frequently referred to as "genetically modified organisms," or GMOs, and the products derived from them are described as "genetically modified," or GM foods. These terms can be confusing, as essentially all cultivated plants have been genetically modified through breeding and selection—for example, the many varieties of cultivated onions possess numerous qualities that distinguish them from each other and especially from the wild onions from which they originated.

### **Application of Genetic Engineering in Agriculture**

The first genetically engineered crops were planted on a large scale in 1996. By 2001 more than fifty million hectares were planted worldwide with transgenic crops. The first generation of these crops has been altered in

ways that improve the efficiency of crop production by modifying the tolerance of plants to herbicides and insect pests. Broad-spectrum herbicides are able to kill almost all plants. A prerequisite for using chemicals to control weeds in a crop is that the crop itself must be resistant to the herbicide. Genetic engineering has been used to develop plants (specifically soybean, canola, corn, and cotton) with resistance to two broad-spectrum herbicides, glyphosate and glufosinate, which are sold under the trademarks Roundup and Liberty, respectively. Glyphosate-tolerant soybeans have been adopted rapidly in some countries, notably the United States and Argentina, and accounted for approximately 46 percent of the soybean acreage worldwide in 2001. Herbicide use has not declined in these crops but the specific herbicides that are used have changed.

Insect pests can damage crops during the growing season and also after harvest. A variety of methods, including cultural practices and insecticides, are used to control insect damage. Genetic engineering has provided novel approaches to this problem. The bacterium *Bacillus thuringiensis* (*Bt*) produces proteins that are toxic to some types of insects, and *Bt* spores have been used as insecticides for decades. Genes encoding *Bt* toxin proteins have been isolated, modified so they function in plants, and transferred into crop plants including corn, potato, and cotton. These engineered *Bt* crops are more resistant to such insects as the European corn borer, Colorado potato beetle, and cotton bollworm than are their nonengineered counterparts. The introduction of *Bt* cotton has resulted in reduced use of insecticides on this crop in some regions of the United States. Growers of *Bt* crops are required to plant a portion of their acreage with varieties that do not carry the *Bt* gene, in an effort to delay the development of insect populations with resistance to *Bt* toxins.

The Flavr Savr tomato, developed in the 1980s by Calgene, a biotechnology company in California, was the first food produced from a genetically engineered plant. These tomatoes ripened more slowly and had an extended shelf life. However, for a number of reasons—including production problems and consumer skepticism—this product was not a commercial success and was withdrawn in 1996, after less than three years on the market. Melons and raspberries have also been engineered to have delayed ripening but have not been produced commercially. Transgenic papayas with resistance to ring spot virus also have been developed. These were grown successfully in Hawaii, where the papaya industry was devastated by this debilitating disease. A similar approach was used to produce virus-resistant summer squash and against other viruses affecting a wide variety of foodstuffs.

The first generation of transgenic crops for the most part were designed to improve the efficiency of crop production, an ongoing objective for genetic engineers. Additionally, the techniques of genetic engineering can be used to alter the nutritional composition of foods. The

transfer into rice of three genes that function to produce beta-carotene in the seed resulted in “golden rice.” Once consumed, beta-carotene can be converted to vitamin A, the degree of this conversion being dependent upon a number of factors that relate to the source of the beta-carotene, the diet, and the individual consumer. In less-developed countries, vitamin A deficiency is widespread among those with a restricted diet, and is responsible for increased mortality and blindness in children. Although the efficacy of transgenic rice in reducing disease has not been established, it demonstrates the potential use of genetic engineering for nutritional enhancement in many crops. Other applications of genetic engineering of animal and human foods include removing allergens from foods such as peanuts, increasing the level of essential vitamins and nutrients in foods, and producing foods possessed of vaccines and other beneficial compounds.

Genetically engineered microbes also are used to produce proteins for food processing. Chymosin (or rennin), an enzyme used in cheese production, traditionally is obtained from the stomach of veal calves. However, the gene encoding this enzyme was transferred into microbes, and the enzyme now can be produced in bulk by purifying it from large microbe cultures. Chymosin prepared from transgenic microbes has more predictable properties than the animal product and is used to produce more than fifty percent of hard cheeses in the United States. Other enzymes used in food processing are produced by similar methods. For example, bovine growth hormone (BGH) is produced in large quantities from transgenic microbes and is given to cows to increase milk production.

### Regulation of Genetic Engineering

In the United States, three federal agencies—Food and Drug Administration (FDA), Environmental Protection Agency (EPA), and Department of Agriculture (USDA)—are involved in regulating transgenic crops. Similar systems are in place in other countries as well. Companies that have developed this technology generally are supportive of the current regulatory framework. Nevertheless, the development of transgenic crops and the introduction of foods that contain products from these plants in the 1990s generated tremendous controversy, notably in Europe. Proponents of genetic engineering have argued that the addition of one or two well-characterized genes into crop plants that have a history of safe use is unlikely to affect materially the properties of these plants. Opponents suggest that this technology has not been tested adequately and the public should not be exposed to unknown and unnecessary food-based risks.

Safety concerns include the possibility that this technology will reduce the nutritional content of foods and introduce novel allergens or other toxins into foods. Opponents have sought more extensive testing and mandatory labeling of products that contain genetically engineered foods so that consumers can choose whether or

not to eat such items. The impact of transgenic crops on the environment also has been questioned. Pests are likely to develop resistance to toxins produced by transgenic plants, raising doubts about the sustainability of this approach. However, transgenic technology also has the potential to reduce the use of chemical pesticides for crop production, which most regard as a positive development. Transfer of genes from engineered crops to other plants might also occur—for example, making weeds resistant to a specific herbicide or expanding the range of a plant so that it can grow in new locations.

This new technology also brings forth social, economic, and ethical issues, many of which are reflected by a wide political debate. One subject of concern is that most of the technology enabling genetic engineering of crop plants is controlled by a small number of companies. Much of this control is achieved through ownership of intellectual property, such as patents on genes, methods to produce transgenic plants, and the plant material that is the basis for crop improvement. Companies that manage agricultural inputs, such as seeds, pesticides, and fertilizers, as well as food processing and retail operations, function increasingly on a global scale. Opponents of globalization have criticized genetic engineering as one factor that is contributing to this trend and have expressed concern that both farmers and consumers will have limited choice in who supplies their needs. Opposition to genetic engineering also has come from religious groups who believe that tampering with genes in this way is unnatural—that is, inconsistent with the divine domain of nature—and should not be allowed.

Development of methods to genetically modify plants that extend beyond the limits of normal sexual reproduction has the potential to change many aspects of food production. Some of the first generations of products of this technology were adopted readily by most farmers but, as with other new technologies, there are many opponents. If this technology eventually receives widespread acceptance, it is likely that genetically engineered products will be found in almost everything that humans and domesticated animals eat.

Genetically engineered foods have caused widespread concern, even open protest, as in the case of this demonstration against the Federal Food and Drug Administration in Chicago. Much of the concern is not centered on the science itself, but on the social and ethical ramifications, the economic implications, and the lack of accountability for “genetic pollution.”

**GENETICS.** Since the first efforts were made to cultivate plants, humans have employed genetics to breed crops with improved taste, hardness, or yield. The long history of genetics and nutrition can be felt even today, and permeates many aspects of our daily life. Home gardeners can purchase seeds that will grow in particular soils, produce fruit at various times of the year, or grow in sunshine or shade. Local supermarkets sell supersweet varieties of corn and fruits such as the tangelo, made from crossing grapefruits with tangerines. The “Green Revolution,” which began with the identification of a high-yield strain of wheat, has resulted in dramatic increases in food production around the world. With the advent

**FIGURE 1**

of genetic engineering, new, disease resistant crops have been developed, with the promise of reducing requirements for pesticide use.

Plants are not the only organism to be subjected to genetic breeding programs by humans. Yeast strains for baking bread or producing alcoholic beverages have been cultured for centuries. Meatier turkeys and cows that give more milk are the product of animal breeding efforts. Some have argued that the genetic manipulation of food-stuffs has gone too far, emphasizing crops that can withstand long storage times, transportation to markets, and handling by the consumer over any selection for flavor. Others worry that genetic engineering gives us unprecedented, and perhaps dangerous, opportunities to mix and match desired traits. It is nevertheless apparent that genetics has had an enormous impact upon society.

What is genetics? Simply put, genetics is the study of hereditary variation. This variation, in essence, is the diversity of life as it exists in all its forms on earth. For example, there are perhaps some 300,000 different species of flowering plants. What makes each of these plants different from one another? Perhaps even more amazing than this variation between species, there are astounding levels of variation that can be found even within a species. There are, for example, some 6,000 different varieties of apples alone. Genetics aims to understand how this variation occurs between species as well as within species. The term "phenotype" is used to describe any differences that can be observed or measured. For example, the possession of yellow kernels is a phenotype of a particular strain of corn, which distinguishes it from strains that possess white kernels. The two may have phe-

notypes in common (e.g., they both have white flowers or are supersweet) in addition to the differing phenotype of yellow and white kernels. Genetics examines the ground rules regarding how these phenotypes are passed on, or inherited, from one generation to the next.

### Gregor Mendel, the Father of Genetics

While genetic breeding has been practiced for many hundreds of years, the true science of genetics began with Gregor Mendel, an Austrian monk who published his seminal work in the mid-1800s. At the time, genes had not been identified; indeed, the term itself would not be coined until 1909. How traits could be inherited from one generation to another was entirely unclear. Charles Darwin himself proposed the pangenesis theory, in which traits from the parents are passed to their children in a process that "blends" them together. In this theory, children represent a melding of the two parental sets of traits. They in turn would pass their traits on to their children, further blending together the traits of their respective parents. This model of how genetics operates can be contrasted with the particulate theory, in which traits are retained on small particles passed from one generation to the next. While Darwin's model would seem to be consistent with what we can observe in our own children, Mendel's carefully performed and insightful experiments clearly supported the particulate theory, and laid down the basic principles of the inheritance of phenotypes.

Mendel discovered his principles working with pea plants, which were raised not only for their experimental value but also as a food source for the monastery. Mendel's seminal idea was to identify clearly defined and distinct traits among these plants, and determine how these phenotypes were passed from one generation to the next. For example, Mendel identified plants that possessed either white flowers or purple flowers, but not both. He then crossed these two different variants with one another (the "parental," or P0 generation), and examined the flower color of the resulting progeny plants in the filial, or F1, generation. If the blending theory were correct, one might expect pink flowers to be produced in the F1 plants. Instead, Mendel obtained only purple flowered plants. If these F1 purple-flowered plants were then interbred with one another, producing an F2 generation of plants, Mendel saw once again pea plants with white flowers. Thus, even though this particular trait (white flowers) had not been seen at all in the F1 generation, it had been retained, and could be recovered in the F2 generation. These results clearly supported the particulate theory.

To obtain his results, Mendel studied the transmission of seven distinct phenotypes among some 28,000 pea plants, and synthesized them into a mathematical model of genetic inheritance. In doing so, he did what had never been done before; he quantified his results. From an analysis of his data, he was able to infer several key principles. He argued that there must exist determinants that

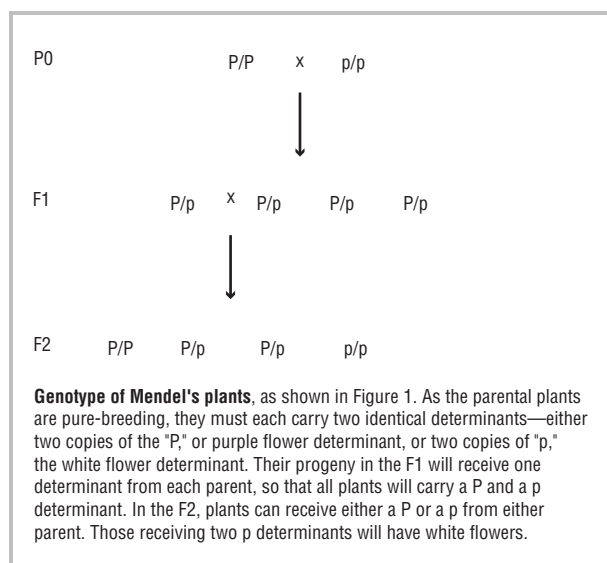

specify particular phenotypes, a feature we now recognize as genes. He also argued that these determinants are located on particles, one of which is donated by the father, and one by the mother. These particles, now known to be chromosomes, produce a progeny plant that has one determinant for flower color donated by the mother, and one determinant for flower color donated by the father. The phenotype of the progeny plant will depend upon the particular combination of determinants it receives from its parents. Mendel deduced that the determinant for the production of purple flowers (represented as “P”) is dominant over the determinant to produce white flowers (represented as “p”). Conversely, the white flower determinant is recessive in the presence of the purple-flower determinant. Two copies of the purple-determinant (P/P) in a plant, one maternal and one paternal, results in purple flowers. One purple and one white flower determinant (P/p) still produces purple flowers. Only if a plant receives two white flower determinants (p/p) will it possess white flowers.

Mendel’s results were not widely known at the time. Some thirty-five years later, his work was “rediscovered” by geneticists who had repeated his results in other organisms. The implications of Mendel’s work were revolutionary. For the first time, it was possible to observe the patterns of inherited phenotypes of a plant, animal, insect, or bacterium, and deduce, with mathematical precision, the expected genotypes of these organisms. It is a tribute to the work of Mendel and others of his time that their results were obtained despite not knowing that genes were encoded by DNA or how genes act to produce the observed phenotype.

### Single Gene Effects

Part of Mendel’s success was due to his implicit recognition that there are two primary types of variation: discontinuous and continuous. In discontinuous variation, a particular phenotype can be found in a population in at least two distinct forms. For example, Mendel’s peas possessed purple or white flowers, and not both. On the other hand, in continuous variation, a range of similar phenotypes can be observed in the population. An example of this among humans might be the observation that noses come in all shapes and sizes. In most instances, genetics has focused predominantly upon discontinuous variants, as the associated phenotypes can be clearly recognized and categorized. As it turns out, many of the phenotypes that fall into this group can be associated with alterations in the function of a single gene. In our purple versus white flower example, the gene that is normally responsible for giving the plant its purple color has been mutated, such that it no longer functions. In the absence of this gene, white, or uncolored, flowers are produced. The different forms of this same gene (P, indicating normal or wild-type function, and p, indicating altered or mutant function) are called alleles. If an allele is widely represented in the population, as is the case

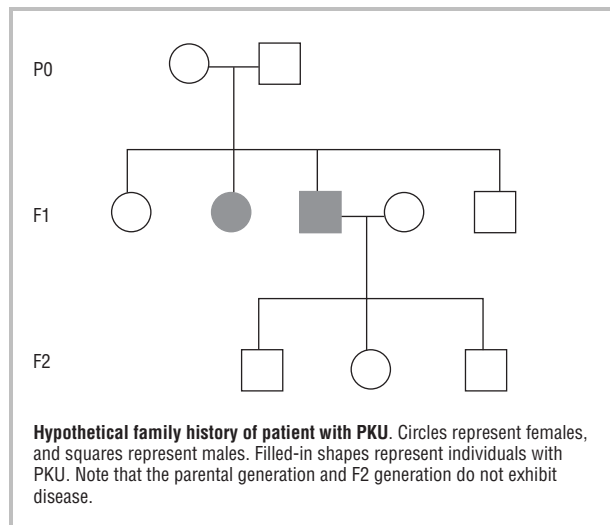

**FIGURE 2**

among white or purple flowers in pea plants, they are termed polymorphisms.

Polymorphisms can be identified in other organisms as well. However, in humans, there are also additional issues of ethnicity and race. A common polymorphism among Asians, for example, is a particular allele of the alcohol dehydrogenase 2 (Adh2) gene. This allele negatively affects the enzyme’s ability to metabolize alcohol, and is possessed by more than 90 percent of the Japanese population. In the European population, on the other hand, less than 10 percent have this allele. Similarly, lactose intolerance is due to allelic variation in the lactase gene. An allele that leads to low activity of lactase following early childhood is common in Africans and Asians (>80 percent), and rarer in Caucasians (17–50 percent). These relatively common polymorphisms are just a few of the many thousands of alleles known to exist in humans.

Why these polymorphisms exist is not clear, although it can be hypothesized that they either do no harm to individuals who harbor these particular alleles, or, if they are in fact somewhat harmful, are nonetheless still of some benefit. This can be described as the fitness of the allele. For example, as many as 10–20 percent of the European population bears a polymorphism in the gene encoding methylenetetrahydrofolate reductase (MTHFR). These individuals have a greater risk of neural tube defects, such as spina bifida, due to the fact that this allele affects folate metabolism. Why then, is such a polymorphism maintained in such a high percentage of the population? The answer may lie in the observation that individuals with this polymorphism have an increased efficiency of blood clotting. As mortality resulting from bleeding after childbirth was a common occurrence, this would be beneficial to individuals bearing this polymorphism. While it is often dangerous to speculate why a polymorphism exists, if this reduction in risk is substantiated, it would

**FIGURE 3**

obviously be of benefit both to the individual and the population as a whole.

While we have centered this discussion around polymorphisms, on occasion, an allele will arise that affects only a small percentage of the population. Although these rare variants are uncommon (<1 percent of the population), they make up a large proportion of the patients that are hospitalized for medically related conditions. One such example would be phenylketonuria, which occurs in one out of every 10,000 births. This medical condition is due to a mutation in the phenylalanine hydroxylase gene, and leads to a failure to metabolize phenylalanine containing compounds, such as aspartame. If unrecognized, infants with PKU invariably develop mental retardation. This can be avoided by monitoring dietary intake to eliminate phenylalanine-containing compounds. How is PKU inherited from one generation to another? The fields of medical genetics and genetic counseling encompass the analysis of family histories, so as to better treat individuals who are at risk from these illnesses. If we examine the family history of a typical patient that has PKU, we might observe the following:

In this case, neither parent in the P0 generation suffers from the disease, but some of their children do. Applying principles learned from Mendel's work, we can infer the genotype of the family members from this phenotypic analysis:

From the study of this family history, it is clear that PKU is inherited in a recessive manner. Adults who are heterozygous for mutations in the phenylalanine hydroxylase gene (K/k; possessing one wild-type or normal allele and one mutant allele) do not have PKU. Only those with two mutant copies (k/k) display the condition. Thus, Mendel's laws apply equally well to humans as they do to peas. Interestingly, however, while the phenotype of PKU patients indicates a recessive inheritance of this

condition, an analysis of the genotype of these patients and the population in general reveals the existence of more than 400 alleles of the phenylalanine hydroxylase gene. This astounding degree of allelic heterogeneity indicates that most PKU patients indeed possess two mutant alleles of the hydroxylase gene, but that these two alleles are likely to be completely different. The phenotypic effect is the same; elimination or severe alteration of the normal function of the gene leads to PKU. The molecular basis of this defect, however, is dependent upon the specific alleles that are involved. It is plain to see that the field of molecular genetics, which examines the actual genes responsible for these defects, is an important complement to more traditional genetic phenotypic observations.

While the examples we have looked at so far have comprised diseases or phenotypic traits that are inherited in a recessive fashion, many diseases are inherited in a dominant manner. In these instances, a single copy of the mutant allele is sufficient to confer, at least partially, a medically associated condition. An example of this might be familial hypercholesterolemia, which is associated with an inability to properly metabolize cholesterol. A family history of patients with this affliction might appear thus:

Compare the rate of occurrence of this condition with that of PKU. Only a single copy of the mutant allele is required to produce at least some phenotype in cases of familial cholesterolemia. In many of these dominantly inherited diseases, individuals that possess two mutant alleles are much more strongly affected than individuals with one mutant and one wild-type allele. In familial hypercholesterolemia, homozygous patients (those with two mutant alleles; H/H) rarely live past the age of 30. These individuals are rare, however, occurring in perhaps one in one million. Heterozygous individuals (those with one mutant and one wild-type allele; H/h), on the other hand, are extremely common, and are present in perhaps one in 500. These individuals have a higher propensity for premature heart disease due to the buildup of atherosclerotic plaques, but without the severity of phenotype exhibited by homozygous individuals.

These examples illustrate just a few of the more than 1400 single-gene disorders that have been identified. It has been estimated that in any one individual, perhaps 20 percent of all genetic loci are heterozygous. This suggests that a striking degree of individuality exists at the genetic level. This allelic variation may explain, for example, the differential response of individuals to environmental, dietary, or pharmacological effects.

### Multiple Gene Interactions

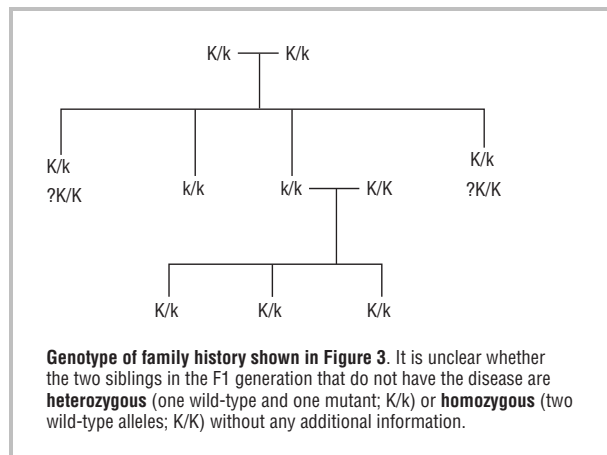

So far, we have discussed examples of phenotypes that can be traced to alterations of a single gene. While great strides have been made in identifying genes that are associated with a particular phenotype, it is clear that we are far from understanding how genes interact with one another as a whole. For example, many genetic disorders

are thought to result from the interplay of multiple genes with epigenetic, or environmental, influences, such as diet. One means of trying to understand these multifactorial disorders and how genes and the environment interact is to examine at a molecular level how genes function. While Mendel derived his results from observing the phenotype of his plants, a molecular geneticist might ask, what is the actual gene that is responsible for production of purple pigment? What is its sequence? How does it function in the plant cell to produce color? With what other genes does it interact?

DNA has often been called the “blueprint of life,” and indeed, DNA is the thread that ties almost all life on earth together. Rules that govern the replication of DNA and its transmission to daughter cells (e.g., during cell division) are the same in nearly all organisms. But if DNA is DNA whether or not it is found within a fly or a human, how is it possible to obtain such diverse organisms? The answer, of course, is that the genes that exist within DNA are different from flies to humans. One might suspect that these two diverse organisms would possess radically different sets of genes, separated as they are by over 600 million years of evolution. With the advent of the Human Genome Project, it has become possible to directly test this hypothesis. Once the entire sequence of human DNA was known, it was compared to the sequence of *Drosophila melanogaster*, a fruitfly that has been used for over one hundred years as a genetic model. This comparison revealed an astonishing 40 percent of all genes in the human have similar counterparts in the fruit fly. While this figure is still tentative, and gene number is hardly an adequate means of comparing differences among species, it underscores yet again that genetic principles learned in model organisms, such as the fruit fly, can have important theoretical and practical applications in understanding human genetics.

If variation between species is accomplished, at least in part, by genes that are unique to flies or humans, how does variation occur within a species? All cells in the human body, with the exception of those involved in the production of sperm or ovum, contain identical DNA sequences, and therefore identical sets of genes. How is it then, that a skin cell will develop differently from a hair cell, if both contain the same DNA? The answer is that each cell may contain the same genes, but not all the genes will be expressed in each cell. Current estimates suggest that there are approximately 50,000 genes in the human genome. Any given cell type, however, is thought to express some 15,000 of these genes. Thus, a hair cell will express 15,000 genes, but these genes will be somewhat different from the 15,000 that are expressed by a skin cell. It is this differential gene expression that leads to the differences in observed phenotype between the two cell types. In a similar vein, two noses located on the faces of two different individuals may well be specified by the same 15,000 genes, but slight differences in their expression from one individual to the next may well explain

**FIGURE 4**

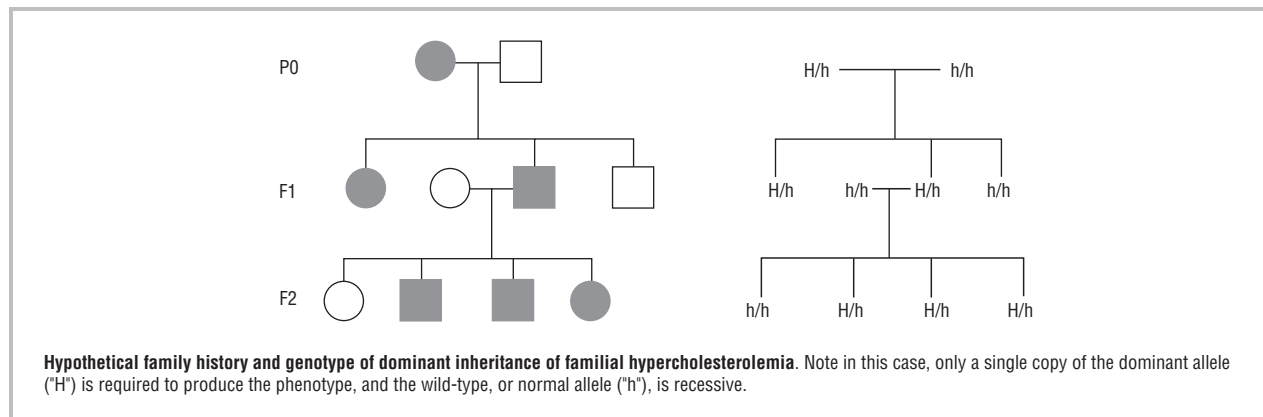

the somewhat petite nose on one and the rather large proboscis on the other. The growing field of genomics aims to study, at a global level, the interactions of all of the genes that contribute toward a particular phenotype.

If it does indeed require 15,000 genes to produce any given cell in the body, then mutant alleles that arise in any one of these genes may, or may not, strongly affect the development of that cell. Alleles of certain genes may alter the color of the cell, or perhaps its ability to metabolize phenylalanine-containing products. Or it is possible that an alteration in just one gene among 15,000 may have no discernable effect at all. How these thousands of genes interact with one another to produce a given trait is perhaps the biggest challenge that faces the molecular geneticist studying genomics today. Moreover, these genetic interactions are often complicated by epigenetic influences as well. Nutrition, in particular, has very strong effects on gene expression. Many multifactorial diseases, such as diabetes, are thought to be associated with both genetic and environmental risk factors. A given family history may, to the medical geneticist, indicate a predisposition towards diabetes, but other factors, such as diet and exercise, are also thought to influence the development of this disease.

One particularly fascinating example of the link between nutrition and genetics is the effect of diet upon aging. Unusual longevity in humans has often been attributed by these self-same individuals as directly associated with the manner in which they have lived their life. Whether it is a glass of wine each day, eliminating red meat, or ingesting large quantities of vitamin C, these individuals claim to have identified the reason behind their advanced years. How much can truly be attributed to these epigenetic influences, and how much is based upon the individual's particular genetic makeup? Research in model organisms such as the fruit fly has identified a handful of genes that seem to strongly affect the lifespan of the fly. Mutations in the methuselah gene, for example, allows flies to survive more than 35 percent longer

FIGURE 5

than their normal lifespan. This astonishing result suggests that aging may actually be strongly influenced by a limited number of genes, many of which are involved in metabolism. On the other hand, it has long been known that reducing the calorie intake of rodents by 40 percent can also markedly increase their lifespan. The new field of genomics has begun trying to identify the molecular basis for this increase in longevity, by comparing how many genes are differentially expressed between calorie-restricted rodents and their non-restricted counterparts. It was found that hundreds of genes had been affected, including a large number known to be involved in metabolic processes. Thus, the effects of nutrition on aging can be profound. How much of this is due to our genes? How much can attributed to single genes? How much is due to our caloric intake? The answer to this "age-old" question remains to be determined.

A similarly tantalizing example demonstrating the link between nutrition and genetics lies in the area of control of bodyweight. Mice that are homozygous mutant for a particular allele of the obese gene (*ob/ob*) are grossly overweight. The excitement that surrounded this result centered around the possibility that weight gain might be strongly influenced by individual genes, and that no amount of dietary control or exercise can alleviate its effects. This, of course, has been shown to be a gross oversimplification, and it is clear that many genes are involved in the regulation of body weight. Nevertheless, it is apparent that the field of genetics is gradually beginning to unravel some of the major problems in nutrition and biology today.

## Conclusions

The practice of genetics is as old as the human race, and yet as a science, it is still in its infancy. The study of genetics stretches across all of biology, and has grown to include many sub-specialties within the field. Cytogenetics, for example, is the study of chromosomal defects, such as trisomy 21. Molecular genetics is the analysis of individual genes, such as *Adh2*, and their function within the cell. Population genetics studies the frequency with

which polymorphisms of *Adh2* occur within large subsets of individual organisms. Medical genetics searches to identify patterns of inheritance of diseases within patients, and the effect of epigenetic influences such as diet and exercise. And finally, genomics tries to understand how genes behave as a whole to specify particular cell types or phenotypes. Together, these diverse but inter-related fields aim to understand how variation is established and maintained within biology.

**GEOGRAPHY.** Food is grown in a one place, distributed to another place, and eaten in yet another place. Food is affected by culture, by economics, and by politics. Food affects our bodies, our relationships with other people, and our relationship with the land. This is the "food system," a system that encapsulates where and how food is produced, how it reaches our mouths, and why we eat what we do.

Anthropologists, nutritionists, historians, sociologists, and philosophers have long been concerned with different aspects of the food system. So too—and increasingly—are geographers.

Geography has a lot to say about food. A subject often misconceived as being concerned solely with maps and mapping, it is actually a philosophically and topically pluralistic discipline that is concerned with spatial processes in the human and physical environment. With a focus on both the spatial aspects of human existence and natural features, geographers are uniquely qualified to study a system that is, as Atkins and Bowler say in *Food in Society* (p. 13), “squeezed into a fault line between environment and society.” Geographers seek to conceptualize the food system as a spatial construct that is driven in part by processes that operate from one physically definable and socially constructed space to another. Scale-dependent concepts such as regional, local, and global, location, place, and space, are the basis of questions geographers ask of the food system: Where is food grown and why? What are the processes controlling the movement of food from place to place? Why do we eat what we do? Why do we buy food where we do? How is food consumption related to production? Why is food consumption high in some parts of the world and low in others? Geographers think spatially. They also think systematically, theorizing about the relative roles of the environment and human beings as participants in the system under study and how they interact.

In the academy there are many different types of geographers, all of whom have a potential interest in food. Physical, economic, social, urban, rural, cultural, medical, and agricultural geographers all have their respective emphases on the analysis of the food system. All told, they study the production, consumption, provision, and distribution of food, from the local to the global, from feast to famine. And, as a tool, geographers can use relatively new computer-aided mapping techniques, especially geographical information systems (GIS) to map and analyze spatial data as it pertains to food systems.

Food production and how and why it varies over space is studied in physical and human geography. Physical geographers seek to explain the spatial arrangement of food crops throughout the world by analyzing the environmental factors that limit or promote food production, such as climate, soil, and topography. Human geographers look to the explanatory power of history, economics, and politics and place a greater emphasis on the role of agricultural (food production) systems in affecting how much food is produced and where. They seek to describe the systems—whether as subsistent, intensive, extensive, or industrial—and ask how social, organizational, and technological changes within the system are affected by spatial processes and how they in turn affect spatial outcomes. Geographers have helped pioneer the understanding of food production as an “industrialized” system, a system bound up with processes of economic development that subsequently affects where and how much food is produced.

Food production also has an impact on the environment. One of the first disciplines to recognize the human

The influence of food production on geography is clearly evident in this aerial view of Kansas farmlands. Circular fields designed to accommodate irrigation systems cluster around a free-flowing river while open grasslands occupy the intervening space. COURTESY OF AP/WIDE WORLD PHOTOS.

impact on the environment, geography has long identified the environmental impact of modern agriculture. Hydrologists and soil scientists measure the impact of fertilizers, pesticides, and irrigation on water and soil quality. Desertification and deforestation are environmental issues identified by geographers as outcomes, in part, of food production. In turn, rural and developmental geographers take up the challenge of assessing the impact of environmental changes on local people and national economies.

In terms of food consumption, geographers argue that “place matters” in what people eat. Traditionally, geography has looked at regional patterns of diet, but over the past three decades focus has shifted to the symbolic meaning and cultural identity of food—to the way, in other words, that human beings use food to construct a place-related identity, either real or imaginary. Cuisines create a sense of identity; restaurant locations indicate spatially spreading food trends; the perception of what is “ethnic” and “local” food reveals the way we see ourselves fitting into society socially and geographically.

Food provision and retailing are another aspect of consumption studies within geography. Geographers seek to explain the spatial patterning of food retailers: Why, in many cases, do certain neighborhoods have very few food stores while others are supersaturated? Using the notion of “competitive spaces,” geographers in the United Kingdom have been able to identify supermarket locating decisions as a response not only to state-imposed locational regulations, but to the market advantage of locating in a “competitive space.”

Geography also asks how spaces of food consumption are linked with spaces of food production. An inherently geographical phenomenon, food is distributed in a variety of ways: national transportation systems, global trade, or local exchanges. Geographers have extended the study of these food distribution networks by seeking to uncover the relations between the site of raw food production and the site of consumption. Using the conceptual approach of “commodity chains,” geographers trace food items from the point of consumption back through the chain of retail, wholesale, processing, and agricultural production, taking into account transportation, labor processes, technology, and politics. And in the related “food network” concept, institutional intermediaries such as state regulation and international agreements are added into the chain. Developments in this field have been spurred by increasing worldwide interest in the trend toward the replacement of national by international institutions, global sourcing of products, and the centralization of strategic assets, trends often conceptualized by the term “globalization.” Geographers have highlighted, in particular, the local, regional, and national response to globalization, often finding that globalization in some way strengthens the local nature of food production.

Linking food production and consumption in terms of supply and demand is also very much part of the geographical tradition. Geographers ask why it is that in some regions and communities of the world people do not have enough to eat, whereas in others there is over-nutrition. Some geographers analyze the spaces of hunger in terms of economics and social relations, others in terms of population growth and environmental limits on food production. Again, geographers are uniquely poised to ask questions about society and the environment. Space, it seems, unites them both.

**GEOPHAGY.** Geophagy, the consumption of earth, is widespread in various animal taxa, including birds, reptiles, and mammals. Among the latter it is reported in rats, ungulates, and primates, and in many human populations. The most frequently consumed soils are generally rich in clay, and the qualities of clay appear to be the stimulus for geophagy. The prevalence of this practice suggests that it is not aberrant behavior, but rather that it may have some functional significance related to diet and ecology. Several overlapping hypotheses have been proposed to explain the existence of geophagy, and clay consumption in particular: (1) clay provides supplemental minerals that may be lacking in the routine diet; (2) clay has the capacity to adsorb toxic secondary compounds widely distributed in plant foods; (3) clay protects the gastrointestinal tract from chemical and biological insult, and thus counters gastrointestinal disease. Support exists for all of these hypotheses depending on ecological context and taxon and indicates that geophagy is likely to be associated with positive biological effects.

The unique chemical structure of clays allows them to have these biological functions. Clays are associated with a variety of soil types, and are formed by routine weathering forces. All clays have similar properties: a large surface area, which derives from the organization of silicon-oxygen tetrahedrons in hexagonal networks, and an ability to bind and exchange minerals because of the dense localization of hydroxyl ions and oxygen in the tetrahedron structures. Clays are commonly composed of aluminum, magnesium, iron, and calcium, which can engage in mineral exchanges. Clays also have colloidal properties that make them adsorbent of water and other organic compounds. Commonly consumed clay types include: kaolin, smectite, montmorillonite, halloysite, and allophane.

Geophagy is well-described among ungulates, which seem to derive significant mineral nutrition (especially

sodium, calcium, and magnesium) from eating earth, and among rats, who appear to use clay to detoxify a highly omnivorous and opportunistic diet. Gilardi and others found that parrots in Peru consumed large amounts of clay-rich soils, which served to detoxify a seed-based diet that was high in secondary compounds and to protect the cells that line the gastrointestinal tract from these toxic chemicals. Within the primate order, apes and monkeys consume soils that contain valuable minerals along with the clay metahalloysite, which counteracts diarrhea.

Among humans, the consumption of clay takes a variety of forms. In some cultural contexts, clay is an integral part of cuisine. Timothy Johns has documented the use of clay sauces with potatoes among highland Andean populations. Consumed in this way, clay adsorbs the toxic glycoalkaloid (solanine) in the potato cultigens that are the staple foods of this region. Clay is also used in the production of acorn bread by both Native Americans and Sicilians (Johns and Duquette, 1991). In this example, baking with clay reduces the toxicity of tannins in acorns, and improves the overall nutrient composition of this food. Clay is also used for specific medicinal purposes, most often to counteract gastrointestinal illness such as nausea, heartburn, or diarrhea (Vermeer and Ferrell Jr., 1985). Consumed in tablet or liquid suspension (as in Kaopectate®), clay has these effects by slowing gastrointestinal motility, binding toxins or pathogenic microorganisms, and buffering acids of the upper gastrointestinal tract. It is important to note that since clay can adsorb a variety of chemical compounds, it can also interfere with the absorption of pharmaceuticals such as antimalarial drugs (chloroquine).

Beyond the routine use of clay in cuisine, clay consumption is often correlated with pregnancy in humans (Lagercrantz, 1958). The practice is reported most frequently among Africans and African Americans, although it is found in many other populations. Women report that clay eases the nausea and vomiting that often occur during the first trimester. This is likely due to the ability of clay to buffer the gastrointestinal tract and adsorb toxins, to which the embryo is especially vulnerable during early development. Clay consumption often continues throughout pregnancy, and clay may provide supplemental calcium, the demand for which increases during pregnancy to form the fetal skeleton. Support for this analysis comes from Andrea S. Wiley and Solomon H. Katz's study (1998) of geophagy in African populations, which demonstrated that clay consumption was significantly more common in populations that did not consume milk and that relied heavily on toxin-rich plant foods. Hence clay may serve as a detoxicant as well as a source of calcium; both are particularly important for nondairying, agricultural populations. Many sub-Saharan African clays (especially those derived from termite mounds) have been found to be rich in calcium (Hunter, 1993). Importantly, clays are frequently baked before consumption, thus reducing the potential for microbial contamination. When clay is not readily available, laun-

## ACORN BREAD

Processing of acorns for consumption is laborious and time-consuming, but the large quantity of tannins in acorns makes them inedible unless some mechanism for their removal is employed. In traditional Native American cuisine, acorns were first hulled (sometimes after boiling, to make it easier to extract the nutmeats) and pounded into a coarse flour with a stone mortar and pestle. Then, a variety of leaching techniques could be employed, including putting the flour in a basket or woven bag or digging a hole in a sandy bank along a river and allowing water to flow through the flour for up to several days. Or the flour could be put in a hole in the ground that was lined with leaves or pine boughs; water was then poured over it numerous times. The leaching removed the bitter tannins, thereby making the acorn flour both more palatable and more digestible. The flour was then placed into a tightly woven basket with water and very hot rocks to make a boiled acorn mush. It could also be molded into patties and fried, or the flour could be dried and then made into a stiff dough and slowly baked in a smoldering fire to produce bread. In contexts where leaching was not practiced or was insufficient to reduce the bitterness of acorns, acorn meal was mixed with clay and water and baked in an earth oven for several hours to produce acorn bread.

dry starch is sometimes consumed by pregnant women, although this is not likely to be associated with the same health benefits as clay.

**GERMANY, AUSTRIA, SWITZERLAND.** These three nations represent the heartland of German-speaking Europe, although their present borders by no means demarcate the farthest geographical extent of German culture and its historical influence. Modern Germany came into existence in 1871 out of an amalgam of petty dukedoms and small kingdoms that traced their origins to the Holy Roman Empire of the Middle Ages. Modern Austria was created in 1918 out of the German-speaking provinces of the former Austro-Hungarian Empire. Its borders have been stable since then. Switzerland's political independence began in 1291 with an uprising led by William Tell, but the long struggle was not complete until 1412, when peace was made with the House of Habsburg. The Habsburgs, who later created the Austrian empire, were originally Swiss, and the ruin of their castle can still be seen in Canton Aargau. While the political evolution of German-speaking Europe is complex, the culinary divisions are far more distinctly defined.

The largest division is based on religion. Northern and eastern Germany are mostly Protestant (Lutheran), while the South is Roman Catholic. Austria is predominantly Roman Catholic. Switzerland is Roman Catholic and Protestant Reformed (Calvinist). These religious differences have had a great influence on foodways and eating habits. In the Protestant areas of Germany, many older religious festivals were discarded. One of the most important changes, however, was the abolishment of fasting except during Lent. The Protestants also gave up the big Carnival processions and the feasting that accompanied them. The German Pietists in particular abjured drinking, gluttony, and carousing with dance. Thus, northern Germany's food habits became markedly different from those of the South. Differences in religion also affected the movement and acceptance of various new customs such as the Christmas tree, which slowly moved south into Bavaria and Austria during the nineteenth century.

While religion has created an overlying framework for the culinary culture of German-speaking Europe, geography has played a fundamental historical role. The Rhine River Valley, which begins at Lake Constance in Switzerland, has been a major cradle of culture for thousands of years. It was the homeland of the ancient Gauls, whose preference for pork and beer is still deeply embedded in German culture. The Rhine Valley became the most important military region of the Roman Empire, and for a short period of time, Trier, Germany, was the capital of the Empire. The vestiges of Roman culture, such as viticulture, sausage making, pretzels, gingerbread, even half-timbered architecture, have all come to represent core features of traditional culture in these three countries. The most significant geographic feature, however, is the Alps, rugged mountains that form a physical barrier between German-speaking Europe and the Mediterranean. The high mountain regions of Bavaria, Switzerland, and western Austria have evolved a cuisine

that is quite distinct from that of the rest of German-speaking Europe. Its focal point is dairying, with milk products and cheese forming the major components.

While the geographic barriers are significant, it is also important to keep in mind that German-speaking Europe is not one monolithic culture. It is composed of many regional cultures and dialects. Alemannic-speaking southwest Germany, Alsace, and Switzerland are home to a very distinct food culture—and the richest agricultural regions—while the Plattdeutsch area of northern Germany, centered on the swampy lowlands bordering the North Sea and the Baltic, offers yet another culinary identity: tea drinking, fish cookery, beer, foods using oats or buckwheat, and very dark rye breads.

Since the 1970s, there has been a revival of interest in dialects and regional cookery and an impressive outpouring of cookbooks exploring local cuisines and food products. This has been a revival in the most literal sense because scholars in all three countries began studying regional foods and foodways in the 1840s; thus the accumulated food literature is extensive and a full century ahead of what has been undertaken in the United States. The *Wörter und Sachen* (Terms and Objects) movement of the early 1900s was particularly active in recording traditional foods and terminologies. Unfortunately, the National Socialist Party, which came to power in Germany in 1933, employed this research toward political ends. Since 1945, the words *ethnisch* ('ethnic') and *Volk* ('folk') in German have carried such a pejorative association with Nazi propaganda that their use is now generally avoided in serious scholarly writings about food.

There is also a sharp dichotomy between the culinary writings of scholarship and the culinary writing of popular cookbooks. Mass-market cookbooks have created the idea of a national German or Austrian cuisine, whereas food scholars have decried this as artificial and misleading, since there are only regional or highly localized cooking traditions, which do not represent the political boundaries of the country. These local traditions often overflow the borders into adjoining countries such as France, Slovakia, Slovenia, and even northern Italy.

### Germany

The present Federal Republic of Germany came into being in 1945 out of the ashes of the Third Reich. It was assembled from the western German states then under Allied occupation, specifically the forces of the United States, Britain, and France. The eastern German states were occupied by the Soviet Union and became the German Democratic Republic. In 1989, with the fall of Communism, the eastern and western states were reunified. The former German states of Silesia, Pomerania, East and West Prussia, and the city state of Danzig (modern Gdansk) are now permanently incorporated into Poland. Since the ethnic Germans living in those areas were evicted in 1945, the culinary cultures of the German regions incorporated into Poland are a matter of history,

although considerable ethnographic material has been preserved from the pre-1945 era. Many traditional recipes from this region, such as *Königsberger Klopse* (Königsberg dumplings) still appear in many German cookbooks. Refugees from these regions have tried to keep their dialects and cooking styles alive through cooking clubs and similar organizations.

There are now thirteen states comprising modern Germany. They include, from north to south: Schleswig-Holstein, Mecklenburg-Vorpommern, Niedersachsen, Brandenburg, Sachsen-Anhalt, Sachsen, Thüringen, Hessen, Nordrhein-Westfalen, Rheinland-Pfalz, Saarland, Baden-Württemberg, and Bayern (Bavaria). Each of these states is further subdivided into smaller regions,

The German Renaissance kitchen as depicted in Balthasar Staindl's *Ein künstlich vnd nützlichs Kochbuch* [An Artful and Useful Cookbook], first printed at Augsburg in 1544. COURTESY OF HANS WEISS. ROUGHWOOD COLLECTION.

some with very distinct local cuisines. For example, the wines and foods of Franconia in northern Bavaria are quite different from the rest of the state; the Pfalz, the southernmost area of Rheinland-Pfalz, is world famous for its wines, and locally well-known for its figs and chestnuts and its onion pies.

It is important to know these German states because popular cookbooks tend to treat regional cookery on a statewide basis—thus, there are Bavarian cookbooks, Saxon cookbooks, and so on. The most detailed cookbooks in terms of local cuisine, however, are the ones that focus on a particular valley or county (*Kreis*), such as Annelene von der Haar's *Das Kochbuch aus Ostfriesland* (The East Frisian cookbook), which deals with an area bordering on the Netherlands. The Frisians are the brunt of many German jokes about gluttony and thickheaded farmers, so this cookbook carries far more symbolism for the German reader than it would for outsiders. A unifying theme in most of the regional cookbooks written today is nostalgia for rural life in the village and a closer tie to nature, even to wild foods. In reality, preindustrial

Germany was a harsh place for peasants, and recurring famine was commonplace.

**Dietary patterns of preindustrial Germany.** Until the beginning of the nineteenth century, mass poverty and famine were integral parts of daily life in most of German-speaking Europe. The majority of the population subsisted on grains that were either eaten in the form of thick gruel cooked in milk or water or converted into flat cakes, coarse breads, a variety of small rolls, dumplings, noodles, and thick soups. (Baker's goods, such as *Lebkuchen*, *Gugelhupf*, *Strudel*, and Austrian *Nockerln*, were rarely made in the home and were eaten only on special occasions.) The grains were rich in carbohydrates and, when consumed in quantity, covered daily energy requirements. Fava beans, lentils, and peas helped to offset the shortage of protein in the grain-based diet. Analysis of the diet in poorhouses and hospices for which records survive has underscored anecdotal evidence of a widespread lack of many vital vitamins and minerals. Thus, various degrees of malnutrition were common in the countryside.

Meat, fish, and butter, as well as eggs, were reserved for special occasions. In general, it was much more common for peasants to sell these food products at market than to eat them themselves. As a result, urban dwellers consumed much more meat, fish, butter, and eggs than their rural cousins. Meat was held in such high esteem that it was viewed as a prerogative of only the well-off and persons of high social rank. It was also abundant only for short periods of time (such as in the fall) and remained expensive well into the nineteenth century. The high status of meat consumption became so ingrained in German culture that today, now that Germans have a high standard of living, meat in some form is usually consumed with every meal. This is nowhere more evident than in the flesh-rich pages of the late Hannelore Kohl's *Culinary Voyage through Germany* (1997), which is a fair representation of what middle-class Germans like to eat.

Most German historians today agree that, by 1800, many of the rural poor and a large portion of the urban working class expended 70 to 80 percent of their income on food, normally in the form of barter. This imbalance was exacerbated by the low consumption of fresh fruits and vegetables until the 1860s. The full value of these foods was not recognized by popular cookbook writers until the 1920s, when there was a large surge of interest in raw foods, fruitarian diets, vegetarianism, and spa cuisine. The German cinema shifted concepts of physical beauty by featuring women who were obviously thin, whereas in the past, a Rubenesque figure had been considered the desired norm. Many books like Sophie Sukup's 1927 *Iss Dich Schlank!* (Eat yourself thin!) proclaimed a new dietary regime based on raw and garden-fresh foods.

Until that time, most fruits and vegetables had been consumed in preserved form, which lowered the vitamin content. Cane sugar was well known to confectioners, and the rich used it in ample quantities, but it never played a role in the German working-class diet. Sugar did not enter that diet in a large way until the introduction of beet sugar. Most German sugar-based products today employ beet rather than cane sugar. Gram for gram, beet sugar is now so much cheaper than meat that it has replaced meat in the form of junk and snack foods.

Until the end of the nineteenth century, a large majority of the rural population in German-speaking Europe was self-sufficient in terms of supplying daily food needs. Most households oriented their menus according to what could be obtained in the nearest market, and these menus did not vary greatly through the course of the year. Regional customs and the season determined the rhythm of consumption, but by today's standards, this cooking would be considered monotonous, nutrient-deficient, hard to digest, even at times disgusting because of the heavy-handed use of lard and other animal fats. It is ironic that with the prosperity which Germany has enjoyed since World War II, culinary writers have painted a picture of the past that is

much rosier than what actually occurred—a truism for most European peasant cookeries. Rich dishes that were only eaten on rare occasions are now treated like daily fare, and restaurants specializing in traditional cookery, especially establishments catering to tourists, provide menus that resemble old-time wedding banquets rather than typical meals. This is not to say that German Europe has not created a cuisine with many noteworthy dishes, yet it is true that these dishes have lost much of their original cultural context.

**Germany's food revolution.** German Europe's gradual transition to a modern diet began in piecemeal fashion. In parts of Prussia, in some of the more enlightened dukedoms and principalities, cottage and small-scale industries were encouraged during the late 1700s. This created a cash economy that allowed the workers more freedom to purchase luxury items like tea, coffee, and chocolate. Northern Germany's dynastic ties to the British crown opened northern ports to English colonial goods. It is not surprising then that port cities like Hamburg and Lübeck now fall within the German "tea belt," while southern cities like Munich are solidly within the confines of the *Kaffeeklatch*.

Tea drinking in the north also brought with it a new preference for white bread and butter as a side dish, and this culinary troika soon displaced the traditional gruels served at breakfast and during main meals. In the south, coffee drinking moved northward out of Austria, accompanied by a preference for sweet pastries eaten with the coffee. This trend also pushed aside traditional gruels, substituting in their stead such innovations as coffee soup (*Kaffeesuppe*), where bits of bread or cake were crumbled into the coffee so that it could be eaten with a dainty spoon.

The rise in white-bread consumption tied to coffee and tea revolutionized German milling practices and changed German agriculture. The growing bread demand caused a shift away from traditional grains like millet, buckwheat, barley, and oats in favor of rye and wheat. Oats underwent the largest decline in consumption even though they were often the grain of choice in many German-speaking regions for hundreds of years. They have continued as a crop largely for cattle fodder, although they are beginning to return as a health food. In spite of the large shift to bread, there were pockets in rural areas where the older gruel-based eating patterns persisted into the early twentieth century.

The second factor in the German food revolution was the coming of the potato. Potatoes had been known in Germany since the 1500s and were grown as curiosities in many botanical collections. Some of the earliest European depictions of the potato appeared in German herbals, yet the plant was largely despised even as cattle feed. Only after the devastating famines of 1770–1771 and 1816–1817 did the potato achieve widespread acceptance. This occurred in concert with efforts by several German

Alpine butter mold from the Tyrol, circa 1890. These molds, which depict mountain deer, edelweiss, and other symbols of alpine culture, were made as mementos for Victorian-era tourists. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

monarchs to encourage the peasantry to rely on potatoes rather than grains and bread as a mainstay of the diet. This promotional effort was in part self-serving since the governments at that time realized that potatoes were cheaper than bread, easy to store, and more reliable than grain, especially in Germany's climate. In terms of yield, potatoes also fed more people per acre than grain. Thus, for a combination of reasons, the potato became one of the "pillars" of modern German cookery, especially in the north. In the south, where flour-based dumplings were a dietary mainstay, the potato never quite achieved the same central dietary role. To this day, the potato is still only a side-dish food in southern Germany, Austria, and Switzerland. It is also converted into dumplings in those regional cuisines.

The third factor that played a decisive role in the German food revolution was the increase in alcohol consumption, especially in the form of spirits or hard liquor. Grain and fruit alcohol was distilled by many peasants in the seventeenth century, but this was mostly to make good use of the residues from wine pressing or from cider. Furthermore, the distilled beverages were treated more as medicine than as social drinks. Around 1800, German chemists discovered that spirits could be distilled from potatoes, and this opened the door to what is known in Germany as the "Brandy Plague" (*Branntweinseuche*). The plague spread in step with the rising popularity of potato production, especially among the large land holders in northeastern Germany. The benefits were obvious: potato *Schnaps* provided yet another source of income for the landowner. Furthermore, the potato scraps left over from distilling could be used to fodder pigs (yet another

sideline business). But cheap *Schnaps* weaned peasant drinkers away from beer to such an extent that production ceased in many areas of Germany, with the result that beer brewing became concentrated in the hands of large urban breweries. The unspoken side effect of the Brandy Plague was the concomitant rise in alcoholism. However, in traditional wine-growing regions, old drinking habits prevailed. The Brandy Plague never touched the Mosel Valley, the Pfalz, or the vineyard villages of Swabia.

After its establishment in 1871, the Second German Reich experienced rapid industrialization and a tremendous population explosion. The growth in the population of cities was accelerated by migration of labor from the countryside. Due to technological improvements in agriculture, the food supply throughout German Europe increased dramatically, and meat consumption rose with it. Fear of food shortages and famine very quickly disappeared almost within a generation. Only after World War I and during World War II did Germany suffer again from widespread food shortages. Today there are roughly 230,000 registered food products available in German stores on a daily basis.

All of these sociological and economic changes in German diet did not go unnoticed by cookbook writers. German-speaking Europe, like England, has a long tradition of middle-class cookbooks that may be studied as barometers of culinary change. The first of these is doubtless the *Kuchenmeistery*, a pamphlet cookbook first printed in Nürnberg about 1485. It was not until the latter part of the eighteenth century, after the appearance of a number of general reflections on the culture of eating, that a true "bourgeois cuisine" began to take shape in German culinary literature. This is referred to in German as *bürgerliche Kochkunst*, a concept which has no precise analogy in English.

The underlying themes of this literature were economy, rational meal preparation, taste improvements over traditional recipes, and new meal regimes under the rubric of *Hausmannskost* (fare for the working husband). This new literature for "plain kitchens" as opposed to aristocratic kitchens appealed to urban housewives. The great German classic of this genre was the *Kochbuch für die gewöhnliche und feinere Küche* (Cookbook for plain and elegant cookery) written in 1845 by Henriette Davidis, the daughter of a Westphalian minister. This book passed through new editions almost every year until 1900—long after the author's death in 1876. Davidis also wrote the first cookbook on the preparation of horsemeat in 1848, and a collection of her recipes was published for German-American immigrants in Milwaukee during the 1870s. She was in every respect reigning queen of the kitchen of imperial Germany.

Towards the end of the nineteenth century, there was a growing recognition in Germany, Austria, and Switzerland that cookbooks had become a mirror of the whole culinary culture. This led to a realization that the

peculiarities of regional cookeries promoted feelings of regional identity and even a sense of nationalism. Cooking literature turned abruptly away from French cuisine in favor of regionalisms, even regional dialect food terms. In some cases, this genre has evolved even further, as in the case of Swabian cookbooks printed entirely in Swabian dialect.

It is possible today to dip into these regional cookbooks to extract a few examples of some of Germany's best-known traditional dishes: *gefüllter Saumagen* (stuffed pig's stomach) of the Pfalz; *Spektorte* (bacon tart) of Saarbrücken; *Panhas* (scrapple) and *Rievkooche* or *Reibekuchen* (shredded potato patties) of Nordrhein-Westfalen; *Schleizer Bambser* (sugary potato dumplings) of Thüringen; Christmas *Stollen* (fruit cake) of Saxony; Nürnberg *Lebkuchen* (gingerbread), *Schmalznudeln* (deep-fried yeast dough), and Franconian *Blaue Zipfel* (sausage stew) of Bavaria; *Käsespätzle* (cheese spaetzle) and *Schupfnudeln* (finger dumplings) of Baden-Württemberg; *Pommischer Mandelkringel* (ring-shaped almond cake) of Mecklenburg-Vorpommern, and *Rote Grütze* (pudding of mashed tart fruit with oatmeal and cream) of Hamburg and Schleswig-Holstein. Not the least of course are *Sauerbraten* and the German pretzel. German pretzel bakeries have even gone so far as to underwrite the continued growing of spelt wheat (*Triticum dicoccum*, var. *spelta*), the ancient grain associated with pretzel making since the early Middle Ages. Spelt, under the label of *Grünkern* (dried unripe whole grains) has also become a symbol of the latest wave in German cookery: green cuisine or ecological fare.

**Green cuisine (Ökokost).** This concept came into being through the German Ecological Movement (called the "Greens"), which promoted a total reassessment of the food chain and its connection to the environment. The movement had its roots in German health-reform movements of the late nineteenth century but adjusted those concepts in more modern terms. Essentially, green cuisine is a cookery in which all agrarian products must be free of artificial ingredients, additives, and chemical taints; only food in its most natural form is acceptable. In general, this type of food is grown by farmers who follow organic growing methods and is very closely connected with the mainstreaming of vegetarianism. Although the Green Party has many followers in Germany and wields considerable influence in several regional parliaments, the overall market for such food was small until 1999. The outbreak of hoof-and-mouth disease and mad cow disease caused a large drop in meat consumption and sent many German consumers in the direction of *Ökokost*. The market sector for this type of food has now trebled, but it is still not the choice of a majority of Germans.

**German cookery today.** Prior to World War II, Berlin was Germany's cultural and culinary capital, although Munich was arguably the "Berlin of the South." With the

Contemporary German cooking is undergoing reinvention in the hands of chefs influenced by French nouvelle cuisine. This study in tomato soup as food and art was prepared at Die Ente Restaurant in the Hotel Schwarzbauch, Wiesbaden, Germany.  
© BOB KRIST/CORBIS.

massive destruction of Berlin's downtown area during the war and the movement of the capital to Bonn, the center of gravity shifted decisively to Munich. Munich remains today the country's most energized culinary center and has attracted many new and creative chefs. It is also home to the *Oktoberfest*, which is known throughout the world for its beer and sausages. The *Oktoberfest* began in the early nineteenth century as an agricultural fair showcasing the products of Bavaria. It was intended to encourage Bavarian agriculture and a sense of national pride (at the time, Bavaria was an independent kingdom). Today, the event has become a tourist mecca and the conduit for a type of tourist cuisine called "Bavarian cooking" that has been replicated in mini-*Oktoberfests* all over the world.

The best German cookery is found in small restaurants and inns, often in the countryside and not far from vineyards. There has been an attempt by many chefs to lighten up the traditional cuisine, to explore unusual local produce, and to reinterpret recipes according to

new dietary demands, such as less fat and smaller portions of meat. Whether this trend will lead to yet another German food revolution, only time will tell.

### Austria

The Republic of Austria was created in 1918 out of the German-speaking provinces of the former Austro-Hungarian Empire. Modern Austria consists of eight provinces plus the capital city of Vienna, which for elective purposes is treated as a province. From east to west, the provinces include Burgenland, Niederösterreich, Oberösterreich, Steiermark, Kärnten, Tyrol, Salzburg, and Vorarlberg. Each of these regions is remarkably different from the other in spite of the small size of the country. Much of the western part of the country straddles extremely high mountains, and this alpine environment has played an important role in the development of regional foods and foodways.

The economic development and general trends experienced by Germany during the nineteenth century also occurred in much of the Austro-Hungarian Empire, with famine and poverty widespread in the countryside. Much of the wealth was concentrated in large cities, especially Vienna, Budapest, and Prague, where the landed aristocracy congregated. When Vienna was cut off from its Slavic and Hungarian provinces in 1918, much of the former industrial development lay outside the borders of the new country. The great imperial city found itself at the hub of a wheel with only a few remaining spokes. Due to the rugged terrain of the western provinces, that region continued to be largely agricultural and pastoral and remains so even today, although tourism and skiing are important sources of local income.

Any discussion of the food culture of Austria must first take into account the enormous historical influence that Vienna has had on the foods and eating habits of the country. But Vienna's role in this culinary evolution is relatively recent. The city was not a capital during the Middle Ages, and during the eighteenth century, when it was home to the Habsburg monarchy, it was still a small town by European standards. It was not until the Congress of Vienna in 1815 that the city established itself as a major center of culinary activity. Vast sums of money were spent during that period and gave rise to the light-hearted party life for which the city became famous. This reputation continued to grow rapidly as Vienna's wealth attracted culinary talent from all over Europe, yet the city did not take on the grand imperial appearance it has today until after the medieval city walls were demolished in 1857. However, several cultural themes came together in a unique way that gave rise to a distinctively Viennese way of life.

The first of these was coffee. There is a degree of murkiness about the origins of coffee drinking in Vienna, yet there is solid archival evidence that it was being drunk in private homes as early as 1665. The first public coffeehouse opened in 1683 and after that, coffee (along with

chocolate and tea) became a common beverage in Viennese establishments frequented by men. It is fairly clear that the coffee habit came to the Viennese via the Turks living in areas then occupied by the Ottoman Empire, but the reasons for coffee's eventually preempting other exotic beverages cannot be ascertained from the historical record. Perhaps it was the association with Turkish luxury, or the fact that coffee could be consumed with very sweet foods to offset the bitterness. Whatever the reason, coffee found a natural marriage with sweet pastries in Vienna, and this union of bitter-and-sweet became the keystone of the Viennese coffeehouses of the nineteenth century. Furthermore, Vienna became the gateway for coffee drinking throughout the Upper Danube Basin. The coffee habit also moved west into southern Germany and Switzerland—accompanied by the silver trays of rich pastries.

Viennese pastries were not invented in Vienna, although they were undoubtedly refined and perfected there. Most of the pastries trace their cultural origins to Bohemia or Hungary or to some other far-flung part of the old Austrian Empire. It was the coming together of these various festive foods that made the Viennese dessert table so distinctive. It was, in fact, a cornucopia of the best Central Europe had to offer. The idea that Vienna had acquired a cuisine of its own began in cookbook literature intended for women who lived in more provincial parts of the empire but who wanted to be thoroughly up-to-date. Anna Dorn's *Neuestes Universal-oder Grosses Wiener-Kochbuch* (Newest universal, or large Viennese cookbook), issued in 1827, is one example of this genre. It lies halfway between the older aristocratic cookbooks composed by royal cooks or anonymous noblewomen and the later *bürgerliche Kochkunst* of Germany. Like the first Polish cookbook, Austria's first cookbook was written by an aristocrat, although the author is as yet unidentified. The cookbook was called *Ein Koch- und Artzeney-Buch* (A book of cookery and household medicine). It was published at Graz in Steiermark in 1686.

Another theme in Vienna's culinary evolution was the creation of a furniture and decorative style now called Biedermeier. It took shape during the 1830s and drew upon neoclassical themes for its inspiration. Vienna produced some of the most extraordinary furniture during this period, combining blond Hungarian oak with dark woods from the hinterlands, and then furnishing coffeehouses and restaurants with the most voluptuous combinations of color and classical ornament. This style of design found its counterpart in foods, and many surviving cookbooks, especially the hand-illustrated ones for professional bakers and chefs, offer an amazing array of richly ornamented dishes so refined in appearance that they must have startled the country bumpkins accustomed to seeing only dumplings and tarts on special occasions. Viennese cooking continued to evolve throughout the nineteenth century, but it never escaped its core identification with Biedermeier style. If this essence of Vien-

nese cuisine could be expressed in a few words, then it has been captured succinctly in Joseph Wechsberg's essay "Tafelspitz for the Hofrat," which describes in minute detail the art of preparing a very special Viennese, and only Viennese, cut of beef.

The third theme in the evolution of Viennese cookery is the *Heurigen*. These are extremely informal family-owned snack-houses whose primary function is to sell light foods to accompany year-old local wines. Authentic *Heurigen* are owned by small-scale vintners who sell their own wines and no other. When the houses are open, the owners hang a pine branch or a wreath of evergreens over the door. Menus consist of cold cuts, bread, sausage, walnuts, perhaps even some home-cooked food, but the meals are not considered dinner. After the close of the business day, Viennese flee to the countryside to spend a relaxed evening in their favorite *Heurigen*. This social institution is very firmly established, but there are also *faux Heurigen* whose primary clientele is tourists seeking out "the *Heurigen* experience." These houses are easy to spot because they are surrounded by buses and cars with foreign license plates.

There are over 140,000 acres of vineyards throughout Austria, mostly planted in the native *Grüner Veltliner* (for white wine). This has given rise to *Heurigen* far beyond the Viennese countryside. While this development is doubtless good business for small places in out-of-the-way locations and is especially beneficial to large commercial wineries, the two institutions are not the same. For Viennese, the *Heurigen* experience represents a momentary return to the countryside, a reality check against the oversophistication of city life and an opportunity to taste "real" Austrian food of the sort grandmother used to make. This interest in culinary roots is something that took shape after World War I, after the country shrank to its present size, and especially after the coming of the automobile, which made evening trips to the country possible.

It is significant that Katharina Prato's great Austrian classic *Süddeutsche Küche* (South German cookery), which first appeared at Graz in 1858 and passed through more than seventy editions, made no mention of Austrian cuisine. Prato was from an aristocratic family, and her world view, like that of other Austrians of her day, encompassed the empire and its most refined culinary riches, not the food of the peasants. By degrees, the *Heurigen* have taken this view in the opposite direction, and this has moved hand-in-hand with Austrian scholarship on the country's most interesting traditional foods and customs.

The list of individuals who have contributed to the formation of a new Austrian culinary identity is indeed long, but two names do stand head and shoulders above the rest. They are Ernst Burgstaller and Anni Gamerith. Both were scholars with an ethnographic approach to their subject, although Gamerith was also intensely interested in traditional horticulture and actively helped to preserve endangered heirloom food plants. Burgstaller's *Österreichisches Festtagsgebäck* (Austrian festive breads and

pastries) is a model of what can be learned about a country by studying its foods on a village-by-village basis. Burgstaller's maps outlining regional customs and foods have formed the basis for many regional food studies that have followed, such as Brigitte and Siegfried W. de Rachewiltz's *Tiroler Brot* (Tyrolean bread). On the other hand, Gamerith's literary output was huge, and many of her studies take a holistic approach to food. *Lebendiges Ganzkorn* (Living grain) followed the entire story of whole-food grains in Steiermark, their agricultural history, the old horticultural knowledge surrounding their planting and harvest, the old methods of milling and storage, and finally, their conversion into food and bread, including recipes.

**Food in Austria today.** Gamerith's approach may have been influenced to some extent by the writings of Rudolf Steiner, whose theories on biodynamic agriculture not only originated in Austria, but are still widely practiced there to one degree or another. Because of the lack of large open agricultural lands, Austrian farmers have concentrated on intensive agriculture on small plots of land. Organic farming is extremely popular, and the country supplies a large amount of its own food. Interest in heirloom fruits and vegetables is high and is well-coordinated under the grass-roots organization *Arche Noah* (Noah's Ark), which is headquartered at Schloss Schiltern. The most recent trend in Vienna's leading restaurants has been a turn away from the old imperial cuisine so popular with tourists, and the placement of new emphasis on seasonal local produce and traditional cooking methods. Thus the cuisine of the countryside is now finding new status on high-end menus in the creative hands of numerous young chefs.

Tourism still plays an important role in Austrian cookery, but the differences between native Austrian fare and what tourists consume are growing ever wider. Travel writers and food journalists created a Viennese experience that the tourist still seeks out, such as a requisite slice of *Sachertorte*, a dish of *Kaiserschmarrn*, coffee at Demels, and the ever-present tins of *Mozartkugeln* (chocolate balls). This is culture for outsiders, a caricature of Austria as highly packaged and as devoid of "authenticity" as the blaring echoes of *The Sound of Music* that roll through the cobblestone streets of Salzburg every summer day.

## Switzerland

Modern Switzerland began in 1291 with the confederation of the three original cantons: Uri, Schwyz, and Unterwalden. After that the confederation grew piecemeal fashion with the addition of several new cantons after the Swiss declared independence from foreign domination in 1648. The last cantons to join the confederation were Neuchâtel, Valais, and Genève in 1815. This created the modern borders of the country. Today there are twenty-three cantons, the largest being Graubünden, Ticino, Valais, Berne, and Vaud. While the country has four

official languages (French, German, Italian, and Romansh), German is the dominant language, especially since it is the language of business and banking. However, it is not the oldest language of the country.

Romansh or Rhaeto-Romance is a relic language surviving from Roman times. A mixture of Latin and Celtic, it was at one time spoken over a much larger part of Switzerland than the present Engadin region in Graubünden where it is now centered. The Romansh Badrutt family brought this cultural milieu to world attention when it established luxury hotels at St. Moritz. However, sister dialects of Romansh were spoken in Austria and, during the early Middle Ages, over much of what is now Bavaria and Baden-Württemberg. In culinary terms, it is the Romansh culture of Switzerland that provides a direct link to the cookery of ancient Helvetia. When the Swiss think of the roots of their culture, and about symbols of cultural identity, it is Romansh and the ancient Helvetians that come to mind. This is their idea of Swissness and is the reason the country's currency bears the name of the Helvetic Confederation.

In spite of the fact that the Swiss gained political independence in 1648, the country never evolved a national food identity. Today, most outsiders probably think of fondue or Emmentaler cheese when they think of Switzerland, but the Swiss are fiercely loyal to their cantonal identities; thus it is much more reasonable to discuss the cookery of Bern, or of Vaud, or of Zürich, than to lump everything together into one pot. While it may be overly simplistic to break the food story down into the major Swiss language groups, it is true that the cookery of the German-speaking cantons is different from the cookery of the French and Italian cantons—yet with a great deal of overlapping.

The peculiarities of Swiss cuisine have been studied in minute detail by the Swiss themselves, and there are innumerable books tackling the subject. For example, Werner Meyer's *Hirsebrei und Hellebarde* (Millet mush and halberds) traces the shifts in Swiss diet that occurred during the late Middle Ages and the 1500s. From a cantonal standpoint, the best studies thus far are those by the Swiss food historian Albert Hauser, who launched a series of cantonal food histories with the publication of *Vom Essen und Trinken im Alten Zürich* (Eating and drinking in old-time Zurich) in 1961. This was followed by similar studies of Bern and other cantons.

Since the Renaissance came early to Switzerland, and since Basel became a great center for the study of humanism, Swiss books dealing with culinary topics have appeared steadily since the 1500s. Yet a peculiarly Swiss identity did not begin to appear until the eighteenth century. Mostly it took the form of cookbooks written for the wives of rich burgers, as in the case of the anonymous *Bernisches Koch-Büchlein* (Little Bernese cookbook), which is known from its second edition of 1749 (and recently reprinted in facsimile). It first appeared about 1720, al-

though no copies have survived of that edition. The contents of the cookbook, while Swiss in the use of the Bernese dialect of German, make no effort to cover Bernese culinary specialties. It is more of a guide to what was then fashionable, with many adaptations of French recipes.

The same could be said of other cantonal cookbooks, such as Crescentia Bohrer's *Freiburger Kochbuch* (Freiburg cookbook), published in 1836. It was not until later in the nineteenth century that the word "Swiss" begins to appear in cookbook titles, no doubt the result of a rising sense of nationalism. One of these books was Jenny Lina Ebert's *Die Schweizerische Köchin* (The Swiss cook), which was published in 1870 and 1871. Like Bohrer's, Ebert's cookbook embraced *bürgerliche Kochkunst*, and the fact that she used the feminine *Köchin* is significant. This was a book intended for housewives.

The overwhelming body of Swiss culinary literature has been written by men for professional cooks. This phenomenon is due to one very important contribution the Swiss have made to the food world: the development of the hotel industry and hotel cookery. The English discovered Switzerland's Alps during excursions to Italy. The romantic landscapes, the quaint chalets, yodeling peasants, hillsides covered with goats, windswept meadows, glaciers—it was a universe far removed from the apple orchards of Kent. It began with the English renting rooms in farmhouses, but the astute Swiss were quick to observe that more rent-paying Englishmen and their families could be packed into country inns with expanded sleeping and dining arrangements, and thus the hotel industry was born. The construction of the Swiss railroad system made it possible for middle-class tourists to reach most parts of the country. By the 1860s, Switzerland was dotted with hotels situated in scenic locations, and considerable advertising copy was devoted to the fact that the fresh mountain air, the crystal-clear glacial waters, and the fresh cheese and butter were far healthier for the constitution than the thick coal smogs of London. In order to run these hotels profitably and efficiently, the Swiss also established training schools in management and in hotel cooking. They are still masters of this industry, and hotel chefs the world over are quick to mention their Swiss diplomas.

In concert with the movement of tourists into the country there was a movement of Swiss talent abroad. Overcrowding of farmland, food shortages, and economic downturns convinced a number of Swiss to emigrate and to apply their talents elsewhere. Dolf Kaiser has traced this migration in his book *Fast ein Volk von Zuckerbäckern?* (Almost a nation of confectioners?), which outlines in great detail how Swiss from Graubünden came to manage the great hotels, confection shops, and cafés of Europe. This emigration included the Delmonico family, which established a well-known restaurant in New York, as well as many, many other famous names in the world of food: Café Josty in Berlin, the restaurant Köhl in

The *Stube* or stove room was the center of family life in the old German farmhouse. The *Eckbank* (corner bench) along the wall served as seating for the one-pot meals eaten from a common bowl. This photograph from about 1900 shows the interior of a south German farmhouse *Stube*. ROUGH-WOOD COLLECTION.

Odessa (Russia), the Café Chinoise in St. Petersburg, Café Tosio in Warsaw, Klainguti & Company in Genoa, and the Café Gilli in Florence, to name a few. If there were one cookbook that served as a text for this expatriate Swiss food network, it was Giacomo Perini's richly illustrated *Der Schweizerzuckerbäcker* (The Swiss confectioner), which was published at Weimar, Germany, in 1852. Because it was written for a small circle of confectioners and thumbed to shreds, very few copies now survive, and it is today one of the rarest of all Swiss cookery books. Furthermore, the term "Swiss" in this context does not refer to a national style of cooking, but to an established reputation among Swiss confectioners for a high level of professionalism.

Swiss confectioners were especially renowned for their chocolates. In 1876 the Swiss confectioner Daniel Peter created milk chocolate by combining milk powder with the chocolate formula. His powdered milk had been manufactured by Henri Nestlé as a product for babies, but it became obvious from this discovery that greater money could be made with this new kind of chocolate. Nestlé's name has been associated with milk chocolate and instant chocolate ever since. Nestlé is now a large international corporation headquartered in Vevey, Switzerland. Another Swiss contribution came from Rodolphe Lindt, who in 1880 developed the technique for conching chocolate, a process that permitted much firmer and more highly ornamental candies, as well as the ability to insert fillings.

**Swiss cooking today.** Tourism has to some extent "decantalized" modern Swiss cooking. In order to meet the expectations of foreign visitors, Swiss hoteliers and restaurateurs are quick to supply a roster of well-known menu items like fondue, raclette, *rösti* (grated potato pancakes), Basler *Leckerli* (Basel-style gingerbread), Zürich Hotpot (*Gumbis*), and a long list of recipes based on lake fish. In Swiss home cooking and in the cooking of the small inns frequented by the Swiss themselves, especially places where there is a fixed *Stammtisch* (reserved tables for regular local customers), the food is decidedly different and at times far superior to hotel fare. There is also a strong movement to capture traditional dishes in cookbooks with a highly localized focus. Fritz Gfeller's *Rezepte aus dem Emmental* (Recipes from the Emmental) represents an attempt by the chef of a popular country inn to take the farmhouse cookery of his famous valley and put it into a cultural context with stories about each recipe and the rather remarkable local characters connected with them. Dialect recipe titles like *Zueguet-Schnitzu* (Schnitzel in the style of a Zueguet farm) tell us that this is a cookbook intended mostly for Swiss eyes.

Likewise, *Aargauer Rezepte* (Aargau recipes) by Dora Schärer, Betty Pircher, and Yvonne Fauser is also a collection of local recipes, but one assembled by three instructors in schools of home economics. They have taken rustic traditional foods and revamped them according to modern cooking techniques and food presentation. This is an important strand in domestic Swiss cooking because

it is an attempt to insulate the nation's cuisine from the homogenization of the European Union, to which Switzerland does not belong.

Finally, it goes without saying that some of the most famous French restaurants in the world are not inside France. The Swiss penchant for high professionalism and artistic creativity in food are perhaps strongest in *Suisse romande*, in the French-speaking cantons facing Lake Geneva. One of the recent culinary heroes of that region is Fredy Girardet, a native of Canton Vaud, whose restaurant in the village of Crissier has been recognized as one of the world's great culinary meccas.

**GINGERBREAD.** The word "gingerbread" has evolved in English over the past five hundred years to include a highly diversified range of ginger-flavored foods. In its original medieval meaning, gingerbread was characterized as a "bread stuff," which meant something edible, a dry finger food consumed as an adjunct to the meal, although in this case unusual in taste and texture, and commonly eaten as a medicine due to its effect on the bodily humors. The earliest references to gingerbread in medieval English cookery books are quite clear on this

point, since they refer to brittle gingerbread preparations made mostly of ginger and sugar. In short, medieval English gingerbread was a medical candy, but parallel to this was a large family of honey-based cakes or cookies known in German as *Lebkuchen*. *Lebkuchen* are the central subject of this discussion. In English they were known as honey cakes.

Honey cakes trace their ancestry to ancient Rome. Among food historians the general consensus is to define the *Lebkuchen* as a highly spiced honey cake baked in a *clebanus* or portable oven. The literal meaning of *Lebkuchen* is thought to be ‘clebanus cake’, something baked originally in the ancient Roman dining room and served directly to the guests. The Romans often baked honey cakes in the shape of a heart, and for this reason their honey cakes were associated with weddings and, by extension, were edible love tokens on a par with the modern box of luxury chocolates. Gingerbread has branched out into several types of cakes or cookies, not all of them sweetened with honey.

By the 1500s English gingerbreads had evolved into highly spiced crisp cookies, like the German *Lebkuchen* ornamented with stamped designs or cut into innumerable shapes and patterns. These cookies were popular during the winter months and were usually dipped in wine or cider when eaten. This is the so-called crisp ginger cake of colonial North America, which survives in the commercial ginger snap cookies. Gingerbread cookies were also popular as Christmas tree ornaments. With the introduction of inexpensive tin cookie cutters during the late nineteenth century and the ease with which cookies could be baked in cast-iron stoves, ornamental gingerbread cookies became a fixed feature of domestic cookery.

The introduction of saleratus and other chemical leavenings during this same period also changed American gingerbread, and soft gingerbread or gingerbread cake developed. In the United States the term “gingerbread” is more commonly associated with a chemically leavened spice cake than with the crisp cookies of the eighteenth and nineteenth centuries.

Prior to becoming a branch of domestic cookery, gingerbread baking of all kinds was generally the preserve of the professional baker. In many European countries gingerbread bakers were a distinct subunit of the bakers’ guild. Since no guilds existed in America, this pattern was not continued there, yet in the German-speaking communities of Pennsylvania and Maryland individuals continued this specialized tradition until the beginning of the twentieth century.

One of the important adjuncts of professional gingerbread baking was the carving of the molds used to stamp the cookies with patterns. Both the carving of molds and the baking of the gingerbreads were male tasks, although the baker’s wife and daughters often worked as decorators. The most elaborate gingerbreads were also

Iced gingerbread from a 1680s mold showing how these cookies looked when fully ornamented. Cookie and icing by William Woys Weaver.

iced, so the ornamental images were not only raised on the surface of the cookies but were also visually colorful. Bakers called this “applying makeup.” Cookies were also gilded with gold leaf, the origin of the idiom “to take the gilt off the gingerbread.” The decorated gingerbreads were often kept rather than eaten, used as wall decorations or put on display in a glass cabinet. Many bakeries made show cookies of giant sizes for their shop windows as part of Christmas advertising. The gingerbread bakers of Belgium and Holland were well known for such large cookies, and considerable literature describes the various schools of mold carving that once existed in those countries.

A discussion of gingerbread and its history invariably turns to a discussion of the molds because the finest ones represent a branch of popular art that has been recognized and studied by numerous European museums. Some of the best-known centers of mold carving were Lyon (France), Nürnberg (Germany), Ulm (Germany), Toruń (Poland), Pesth (Hungary), and Prague (Czech

Gingerbread mold depicting Willem III (1650–1702) of the Netherlands. Early-nineteenth-century copy of an older design. The stadtholder was a popular theme with Dutch gingerbread bakers. Republic). The Bread Museum in Ulm, Germany, and the Ethnographic Museum in Toruń, Poland, possess two of the largest mold collections in Europe.

Molds were an important means for mass producing a design. But to make honey cakes, bakers had also to process honey by removing it from the combs. Thus in the workshops where honey and beeswax were processed, two different types of molds were used, one for gingerbreads and one for wax figures. For the production of gingerbreads, the molds were carved into wooden blocks. The wood had to be hard, for example, oak or boxwood, since a single mold had to serve for the production of thousands of gingerbreads.

Carved molds were made either by special carvers or by the gingerbread bakers themselves. The bakers had to

learn how to carve molds during their apprenticeships and as journeymen. Of course not everyone had great talent for carving, but at least every baker could produce molds as they were needed, for instance, when a mold was too worn out for further use and had to be replaced, when a new motif was in demand, or when a special design had to be made to order.

The characteristic ingredients for the gingerbread dough were honey, flour, and potash. The dough was normally made in the fall and allowed to undergo an enzyme reaction over a period of two or three months. The dough became soft and rubbery, but it was also rather dry in texture and required considerable strength to be handled. It was pressed into the mold and then “beaten out,” that is, the baker slapped and punched the backside of the mold until the gingerbread relief fell out. One journeyman or the master baker produced hundreds of cookies a day. In the oven the cookies with their raised patterns were dried at a low temperature rather than baked in order to preserve the image and keep it from warping.

The range of motifs was wide, and even a simple workshop in the country had a number of different motifs in stock. Foremost among them were hearts, babies, and riders, which can be called classical motifs. Next are the motifs referring to the great feasts of the Christian calendar, such as Christmas and Easter, and the great events in human life, especially the wedding, which was the climax in the life cycle for the individual as well as for the community. When noble families combined forces by marrying their children, usually a so-called “allied coat of arms” was created and carved. Stamped gingerbreads showing this motif were handed out among the wedding guests. Producing offspring was a main aim of marriage, therefore the bride could be presented with gingerbreads showing babies, tokens of well wishing and wishful thinking at the same time.

As far as the Christian calendar feasts were concerned, Christmas motifs took the lead. Among them, the Nativity and the Adoration of the Three Kings were most frequent, but other aspects, such as the feast day of Adam and Eve on 24 December, were represented also. The depiction, especially of these Christmas motifs, was often in the Baroque style because the designs reached their most elaborate forms during the 1600s. However, when such molds had to be replaced, the new carvings were often copies of the worn-out pieces, even including the dates of the originals. Thus a gingerbread mold made as late as the middle or even the second half of the nineteenth century can show all the stylistic criteria of two hundred years earlier.

In Catholic areas the range of religious motifs also included various saints and places of pilgrimage. The religious gingerbread reliefs were bought for the respective occasions. The big Christmas and Easter gingerbreads were shared by the family. The name day (saint’s day) was more important than the birthday (the name day was interpreted as the day of the heavenly birth); conse-

quently a gingerbread relief of the patron saint was often presented to a person as a present on his or her name day. Going on a pilgrimage was a common and regular event. A gingerbread depicting the miraculous image of the place of pilgrimage was carried home. (The custom survives, with paper replacing the gingerbread memento.)

A considerable number of gingerbread motifs were dedicated to news, and gingerbreads served as a kind of history book or newspaper. The “portraits” of emperors and kings or empresses and queens (for example, of Empress Maria Theresa of Austria-Hungary or of Emperor Charles the Great) were presented to the public in gingerbread images as well as in copperplate engravings. There were pictures of the giraffe the Egyptian ruler Mehemed Ali gave to the Austrian emperor in 1828 and of the first steamship on the Danube, the *Maria Anna*, as well as a portrayal of the 1817 European famine that was actually a sociocritical parody of the exorbitant prices of grain. These images represented the big news of the day.

The gingerbreads were sold in the workshops and on the markets. The producers went to the seasonal markets during the year but also set up their stalls on the place before the church on Sundays. The churchgoers were regular customers attending Mass and market together. Gingerbread reliefs were presented to children and grown-ups alike. For children they were sweets and toys (especially babies, riders, soldiers, swords, pistols, trumpets, animals, and at the beginning of the school year, alphabets and school scenes).

Gingerbread molds are no longer produced or in use commercially. Plain gingerbreads, that is, without reliefs, are common. Saint Nicholas, visiting the children on the evening of 5 December, always has gingerbreads among his gifts, and gingerbread hearts with written axioms (“With Love!” “For Friendship!”) can be bought at fairs. Gingerbread molds have become collector’s items and often are quite expensive since few have survived.

**GOAT.** Goats are one of the earliest domesticated animals, providing humankind with milk, meat, hides, and fiber. They include several species of small, cloven-hoofed ruminants constituting the genus *Capra*. Similar to other ruminants, including cows and sheep, goats process plant roughage through a fermentation process within their compartmentalized stomachs, and they chew regurgitated, partially digested food known as cud.

## THE LAND OF MILK AND HONEY

The Talmud explains that the biblical description of a land “flowing with milk and honey” actually refers to goats foraging in fig trees. The figs were so ripe that sweet juice (called fruit honey) dripped everywhere, and the goats were so well-nourished their udders overflowed with milk. The milk and honey literally spilled across the land.

—Ketubot 111b, Megilla 6a and Ramban, Shmot 3:8.

\*

The Old French word for slaughtering and cutting up meat is *boucheron*, from the term for a he-goat, *bouc*. It is also the root of the English words “butcher,” “buck” (a male goat), and, perhaps, the slang term “butch.”

Unlike other ruminants, goats are agile browsers, preferring to reach upwards for foods such as the leaves, fruit, and bark of small trees rather than grazing on grasses. When the desired foods are unavailable, however, goats will consume any plant material accessible. It is this foraging ability and flexibility of diet that has secured the importance of goats as a food source in the world’s subsistence economies.

### Domestication

Wild ancestors of modern goats, known as Persian or Bezoar goats (*Capra aegagrus*) once roamed from South Asia to Crete. It is believed human goatherding began 10,000 years ago in the Zagros highlands of western Iran, as evidenced through selective slaughter of young males. DNA studies support that domestication began at that time due to the rapid growth of the goat population. Domesticated goats (*Capra hircus*) demonstrate remarkable genetic uniformity worldwide. Genetic analysis suggests that goats were a commonly traded in ancient times, which dispersed the population to Europe, Africa, and Asia. Later, they provided a convenient source of milk and meat aboard the ships of European explorers, who introduced goats to the New World.

### Breeds

Selective breeding of goats has resulted in animals smaller than their ancestors, and with greater diversity of coat length, texture, and color. Noses are straight or convex; ears vary from negligible external organs to pendulous and droopy. Both males (bucks) and females

(does) are horned. Hornless (polled) animals have been bred, though the recessive polled trait is associated with infertility. (Goat horns are frequently removed after they bud to prevent accidents.) One characteristic that has not changed with domestication is goat intelligence, judged superior to that of dogs. Numerous breeds have been developed for meat, milk, and fiber (including angora for mohair, and cashmere), in addition to being bred for hardiness and suitability to specific geographic regions.

### Distribution

The Food and Agriculture Organization of the United Nations estimates that in 2001 close to 693 million goats were kept worldwide, with 95 percent of all stock found in developing countries. This compares to 1.3 billion cattle and 1 billion sheep. Regionally, South Asia has the most goats, with 205 million head, followed by East and Southeast Asia, due largely to the 157 million in China. Other nations with significant goat populations (in descending order) are India, Pakistan, Bangladesh, Iran, Nigeria, Ethiopia, Burkina Faso, Brazil, Indonesia, Kenya, Mali, Mexico, Mongolia, and Somalia.

Official statistics on goat meat and milk greatly underestimate production since many goats are raised for personal family use. Primarily nations with large numbers of animals accounted for the most meat: over one-third of the global supply in 2001 came from China. Other significant producers include India, Pakistan, Bangladesh, Nigeria, Sudan, and Iran. Commercial milk production did not correlate so closely with number of head, however, reflecting cultural differences in dairy food use. In 2001, major producers were India, Bangladesh, and Sudan, followed by Pakistan, Somalia, Spain, Russia, France, and Greece.

### Goat Products

**Meat.** Goat meat has a taste similar to mutton, with a slightly gamy flavor. It is lower in fat than either beef or mutton (due to a fat layer exterior to the muscle rather than marbled through it), and can be drier. The United States Department of Agriculture describes quality goat meat as firm and finely grained. The color can vary between females and males, from light pink to bright red. Kids, defined as under one year old, are often slaughtered at three to five months of age. Their meat is less flavorful and juicy, but more tender than the meat of older goats.

Goat meat is an important protein source in South Asia, the Middle East, and Africa. It is consumed regularly in some parts of Latin America, such as the Caribbean, Mexico, and Brazil, and is regionally popular in China, Korea, Indonesia, the Philippines, Greece, Italy, Portugal, and Spain. The entire goat is usually consumed. An eviscerated carcass is typically cut, flesh and bone, into cubes for stewing, used in dishes such as curried goat and

garlic-flavored *caldereta*, a Spanish specialty found also in Latin America and the Philippines. Roasted goat is popular worldwide, often considered a special-occasion food. In Saudi Arabia, the cavity is stuffed with rice, fruits, and nuts. Jerked goat leg, heavily seasoned before cooking over allspice wood, is a Jamaican specialty.

Organ meats are eaten, too. Goat's head soup is prepared in most regions where the meat is consumed. The dish is known as *isiewu* in Nigeria; the eyes are considered a delicacy. In Morocco, kidneys, liver, heart, lung, and pancreas are added to the meat to make goat *tagine*. In Kyrgyzstan, the testicles are roasted separately over the fire for consumption by men, and washed down with vodka. In the Philippines, *paklay* is an Ilocano specialty that combines goat intestines with sour fruits, such as unripe pineapple.

There are few taboos regarding goat meat, and it is accepted by all major religions that permit eating meat. Jewish consumption is often dependent on kosher processing, and for Muslims it must be slaughtered according to *halal* rules. In some regions goats, especially kids, are associated with certain religious holidays, particularly Passover, Easter, and Ramadan. Goat meat is usually classified as a hot or *yang* food in the Chinese philosophical system of yin/yang, and preferentially consumed during the winter months.

Goat meat is not well-accepted by a majority of Americans due to negative associations with garbage-eating and the unpleasant odor of the buck during rut. Exceptions are found among ethnic populations and in the Southwest, where Spanish-Mexican influences have popularized barbecued or pit-roasted *cabrito* (suckling kid). Enterprising goat ranchers in the United States market goat jerky and sausages as *cabrito*, or as the more French-sounding *chevon*.

**Dairy Foods.** Goat's milk is traditionally consumed fresh, fermented as yogurt, and processed into butter and cheese. While goat's milk is a significant protein food in areas where grazing land is limited, goats lactate seasonally and produce lower quantities of milk than do cows, reducing availability. Fresh milk is a common beverage in South Asia, parts of the Middle East, and Greece and is an occasional dietary addition in other goat-raising nations (with the exception of China and Korea). In Europe, evaporated, canned, and powdered goat's milk products are popular. Cow's milk desserts are occasionally made from goat's milk as well, such as ice cream or the Latin American caramelized milk sweet known as *dulce de leche* or *cajeta*.

Goat's milk cheeses are favored in the Middle East, and in parts of Europe and Latin America. They are processed and classified similarly to cheeses prepared from other milks. Soft and semisoft unripened (unaged) cheeses predominate, often home-made. Most are delicate, spreadable, snowy white in color, with a light, tart flavor. Many are marketed under the generic term

Milking a goat herd in Palestine, circa 1915. While men or boys may have tended the goat herds, it was the traditional role of the women to milk the goats and to make goat cheese. ROUGHWOOD COLLECTION.

*Chèvre* (French for goat's cheese) and may be named for their shape, such as buttons or pyramids. Fewer firm and ripened (aged) goat's cheeses are produced; examples are *Crottin* and *Sancerre*. Some cheeses traditionally made with goat's, cow's, or sheep's milk blends include Feta, *Fromage Frais*, *Gjetost*, *Kaseri*, and *Queso Fresco*.

### Health Value

**Meat.** Goat meat is nutritionally notable for combining the advantages of red meat with those of white meat or poultry. Goat meat provides similar amounts of protein when compared to the composite nutritional value for beef, but is 80 percent lower in total fat, most of which is unsaturated. Goat meat is also lower in fat than pork, lamb, and skinless chicken breasts. Iron content in goat meat is 70 percent higher than in beef and 200 percent higher than chicken. Cholesterol levels are similar to beef, pork, and lamb, however.

**Milk.** Goat's milk is a vitamin- and mineral-rich protein food (see Table 1), shown to be a suitable substitute

Goats metabolize and process the yellow- and orange-colored carotenes found in plants much more efficiently than do cows, which is the reason the milk is white, not cream-colored, and the fat is colorless (a drawback for butter).

\*

Xanadu cheese, which blends a mixture of cow's and goat's cheeses, was popular in the American South during the nineteenth century. It was a staple food for the Union Army while in the South, and was so disliked it was banned from consumption after the South was defeated.

for cow's milk in feeding malnourished children. Yet, it is the differences in the fat, protein, and carbohydrate composition of goat's milk that account for its reputation as a healthy food. The fat contains a high proportion of small- and medium-chain fatty acids, which increases absorbability and contributes to the tangy flavor. It is lower in casein proteins than is cow's milk, resulting in much smaller curd (protein clump) formation in the stomach, another factor in digestibility. Goat's milk is naturally homogenized because it also lacks the protein agglutinin, so the fat stays dispersed in the milk and does not form cream at the top. Lactose, a sugar found in all milks, is slightly lower in goat's than in cow's milk, so individuals with lactose intolerance (the inability to digest lactose, resulting in intestinal discomfort) may tolerate goat's milk better.

Goat's milk is often touted as an alternative for individuals with allergies to cow's milk. Goat's milk may be better tolerated, yet it can cause adverse reactions in individuals who are extremely sensitive to caseins or other proteins, such as lactoglobulins. Conversely, individuals who tolerate cow's milk may show sensitivity

to goat's milk. Some parents of infants and toddlers prefer goat's milk to cow's milk or formula due to its superior digestibility, but nutritional adequacy is dependent on fortification, particularly folate. Use of unpasteurized (raw) goat's milk or dairy foods has serious health risks, including brucellosis, listeriosis, staphylococcus infection, salmonella poisoning, and toxoplasmosis.

**GOODFELLOW, ELIZABETH.** Elizabeth Goodfellow (1768–1851) was an American pastry cook, confectioner, and cooking school instructor. Her full married name was Elizabeth Baker Pierson Coane Goodfellow. Through her daughter Sarah Pierson, the wife of the French Quaker Michel Bouvier, Goodfellow was an ancestor of Jacqueline Bouvier Kennedy Onassis. Illustrious connections aside, Goodfellow's antecedents remain obscure, though she was probably born in Maryland, and the source of her extraordinary culinary training is unknown. Yet as an advocate of native ingredients and of an American style of cooking, she was one of the most creative forces in American cookery during the early nineteenth century. She was a teacher, friend, and mentor to Eliza Leslie, who expounded Goodfellow's culinary philosophies in all of her highly successful cookbooks.

By the time of her third marriage, to the Philadelphia clockmaker William Goodfellow in 1808, Elizabeth Goodfellow had established herself as one of the leading pastry cooks and confectioners in the city and had become well known throughout the country for her cooking school, which she operated in association with several

### **“MRS. GOODFELLOW’S INDIAN MEAL POUND CAKE”**

The structure of this recipe is pure Goodfellow. Even though the ingredients are not listed in the order in which they are used, a certain logic emerges, since the weights of the dry ingredients depends on the eggs. The Indian meal referred to was a coarse, starchy flour made from Menomonee white flour corn that resembled *masa harina*.

Eight eggs

The weight of eight eggs in powdered sugar

The weight of six eggs in Indian meal, sifted

Half a pound of butter

One nutmeg, grated, or a teaspoonful of cinnamon

Stir the butter and sugar to a cream. Beat the eggs very light. Stir the meal and eggs, alternately, into the butter and sugar. Grate in the nutmeg. Stir well. Butter a tin pan, put in the mixture, and bake it in a moderate oven. (Leslie, 1828, p. 61)

*Carte de visite* with the photo portrait of Elizabeth Goodfellow. Copied from a daguerreotype about 1851 and probably given out as a memento to guests at her funeral. This rare portrait was discovered by genealogist Francis James Dallet and acquired by the Roughwood Collection in 1997. COURTESY ROUGHWOOD COLLECTION.

boarding schools for young girls. In her cooking school Goodfellow prepared budding debutantes for marriage by teaching them recipes for rich sideboard dishes, like beef à la mode, and innumerable pastries and cakes for formal teas, including her own inventions Spanish buns, Indian meal pound cake, rose jumbles, and perhaps her most famous dish, lemon pudding, the prototype for the American lemon meringue pie.

The core of Goodfellow's lectures survives in Leslie's *Seventy-five Receipts for Pastry, Cakes, and Sweetmeats* (1828) and in numerous manuscript cookery books compiled by other Goodfellow students. Unlike her contemporary and business competitor Hannah Hungary Widdifield, Goodfellow never published a book. One of her former students from the South issued a cookbook in 1853 called *Cookery as It Should Be* and claimed that it

embodied all the best of the Goodfellow school of cookery. It did not, as Leslie curtly pointed out in a contemporary review, since Goodfellow would have been “horrified” by the use of chemical leavens and other glaring culinary flaws.

Leslie’s work preserves Goodfellow’s maxims, such as the one relating to pound cakes: “Up-weight of flour, and down-weight of everything else” (p. 520). One of Goodfellow’s most important contributions was to insist that, in recipe writing, all ingredients be listed first. On this point alone she was many years ahead of her times.

**GOVERNMENT AGENCIES.** National governments often play a major role in the production, distribution, trade, and safety of food. Nowhere is the government food system as elaborate and extensive as in the United States. Bureaucracy in every type of political system has been built up around food regulations and laws; inspection, quarantine, laboratory analysis and certification; epidemiology and surveillance of food-borne disease; and systems management. Which agency performs which function varies among governments.

In any country, there is a fundamental need to sustain as much production as possible in order to feed the population. Government-controlled price-support systems are often put in place to guarantee a certain amount of commodity production. These systems stabilize income for farmers, who supply essential crops, and they allow for competition in domestic and global marketplaces. A Ministry of Agriculture usually performs farm-aid services, in which plant and animal pro-

duction are combined, or such tasks may be undertaken by a more comprehensive Ministry of Agriculture, Fisheries, and Forests, which also oversees fishing and wood production. The function of such agencies may include introducing new technologies to enhance production, as well as educating consumers about new products, such as those derived from agricultural biotechnology. Agricultural agencies may also dispense government-subsidized seed stocks, license plant hybrids, and manage national grain reserves to protect the country against famine. Agency experts or advisory committees made up of outside experts may compile government manuals of good agricultural practices. Regulatory officials in such agencies are responsible for defining regulations that assure food safety and high-quality products for trade. Such officials may also represent national trade interests and work to harmonize international regulations with officials from other countries in arenas like the World Trade Organization or Codex Alimentarius.

It is often said that hunger and food-supply problems in many countries in the developing world are not the result of a lack of food but of a lack of infrastructure for the equitable dissemination of food. Effective governmental management of distribution systems (roads, railroads, etc.) through a Ministry of Transportation can be of vital importance in feeding a population efficiently. A Ministry of Commerce may also assist both in domestic distribution, through oversight of the marketplace, and in international distribution, through a system of import and export regulations, tariffs, permits, and certification, which may also be the tasks of a Ministry of Trade.

A Ministry of Public Health may be involved in issues of food safety and nutrition. This agency is usually responsible for licensing or running analytical laboratories and may be involved in tracking food-borne disease outbreaks. International trade standards enforce low tolerances for agricultural chemicals and pesticides, filth, toxins, and contaminants. Thus, foods that enter into international trade may be of higher quality than those that are relegated to the domestic marketplace, thereby creating a double standard for food production. As a result, domestic consumers in developing nations may receive inferior-quality food, in addition to insufficient amounts of food. A Ministry of the Environment may be a governmental player in the food production arena as well, since pesticides and chemicals used in food production may exert a negative impact on the environment.

Traditionally, this multi-agency situation in governments has set one agency against another, vying for political support and the finances to run programs, especially when resources are extremely limited. A government that encourages interaction among various agencies is often more successful. Due to the heavy emphasis that has been placed on food safety in most nations, there has

## WORLD HEALTH ORGANIZATION

The World Health Organization (WHO), an agency of the United Nations, addresses food safety and food-borne illness, among many other issues. It focuses largely on providing national governments with expert and technical advice on food regulation and the improvement of food safety programs. Along with the Food and Agriculture Organization (FAO), the WHO created the Codex Alimentarius Commission, which publishes guidelines for production, processing, and manufacturing of foods to facilitate international commerce. The WHO also develops and publishes information for food handlers and consumers in an effort to prevent foodborne illness. It collects data on food-borne illness to help guide national and international policies and interventions.

The WHO examines new technologies, such as food irradiation to kill pathogenic organisms, by investigating and publishing reports on the benefits and drawbacks of the technologies. In conjunction with overseeing Codex activities, the WHO seeks to reduce barriers to the world food trade caused by unnecessary or unscientific regulations.

The WHO provides advice to travelers on the consumption of food and water, including the dictums "Make sure your food has been thoroughly cooked and is still hot when served" and "Cook it, peel it, or leave it" for fruits and vegetables. In addition the organization provides information regarding what to do if the precautions fail and the traveler develops diarrhea. The WHO has published "Essential Safety Requirements for Street-Vended Food" to address a common but largely unregulated worldwide food distribution system. It also publishes "Guidelines for Drinking-Water Quality" and technical reports on food additives, drug and pesticide residues in food, and the development of dietary guidelines, among other topics.

*Richard L. Lobb*

been a trend toward the establishment of single national food-safety agencies. The trendsetter in this regard was Canada, which is serviced by the Canadian Food Inspection Agency (CFIA). The CFIA combined into one agency the authorities of four traditional departments involved in food-safety regulation and quality control of food production and processing; export certification; and import permits and quarantine. The French Food Safety Agency (AFSSA) and the new Belize Animal Health Authority (BAHA) are two other examples of consolidated agencies.

The effective performance of all functions involving the food-supply chain is vital to sustaining leadership in government. Without an adequate or safe food supply or a viable economy resulting from ample agricultural production, a hungry public may challenge or overthrow that leadership. The appointed officials who lead these governmental agencies face intense political pressures. Thus the tenure of such an official may be quite brief, with Ministers of Agriculture staying in office an average of fourteen months in Latin America in 2000. First in Great Britain and then in several other European countries, the leadership and structure of agencies responsible for food safety were completely changed in the wake of "mad cow" disease scandals. Public confidence in the government's ability to protect public health plunged to new depths, and whole parties in power were overthrown. In a world where information flows quite freely, governmental agencies are expected to function transparently and keep the public well informed of issues involving the safety of their food supply.

A relatively new tool for regulatory decision making in regard to food production and processes is risk assessment. To appease a wary public and facilitate operations, some governments are adding new agencies to provide such scientific analysis and make recommendations for risk management and communication. The European Union (EU) is setting up an umbrella food-safety agency, the European Food Safety Authority (EFSA), which will provide risk assessment and scientific advice to the European Commission, its Parliament, and member states, as well as to the public. Japan is also setting up an independent scientific risk-assessment authority to reestablish public confidence in that government.

The extent of a government's food-agency infrastructure depends on the importance of agriculture to a national economy and, of course, the size of that economy. Thus, in the developing world, agencies that exist may be extremely important but may have limited capacity and resources. Food agencies in such countries may rely heavily on private sector partnerships where some functions, particularly those involving trade, may be performed by cooperatives of producers working in their own best interests. An example is the Association of Exporters of Chile (ASOEX), which devised a quality production system for Chilean fruits and financed legal costs

associated with allegations of grape dumping in the United States.

**GOVERNMENT AGENCIES, U.S.** Several departments and agencies of the United States government have responsibility for various aspects of food production, marketing, regulation, safety, and consumer protection. Government agencies serve a multiplicity of purposes, but the net effect of U.S. government policy is to provide an abundance of food at relatively low cost.

The United States Department of Agriculture (USDA) has prime responsibility for encouraging agriculture and food production, which it does through a host of programs aimed at the farm community. It administers a program of price supports for major commodities, such as corn, wheat, rice and soybeans, which makes payments to farmers if the market prices fall below target levels. The program is viewed as a "safety net" for farmers and as a boon to consumers since it calls forth abundant supplies of basic commodities. It has the potential of costing the government billions of dollars per year, the actual amount depending on market prices. The existence of such enormous subsidies is often an issue with the United States's international trading partners, despite the fact that many of them also subsidize their farmers.

Prices of other goods, such as milk, are supported through federally enforced marketing orders that set minimum prices paid to farmers. Programs for specific crops of fruits, vegetables, and nuts are intended to stabilize supplies and market prices. Some crops, from almonds to avocados, and some animal products, such as beef, pork, and milk, have programs supported by producers and enforced by the government to raise money for advertising and marketing.

Food safety is a major concern of several agencies, including the USDA's Food Safety and Inspection Service (FSIS), the Food and Drug Administration (FDA), and the Environmental Protection Agency (EPA). FSIS provides mandatory, carcass-by-carcass inspection of slaughtered livestock and poultry to ensure that meat and poultry products are wholesome and not adulterated. At the turn of the twenty-first century, more than seven thousand FSIS inspectors work in meat and poultry plants across the country; some states have equivalent, federally recognized programs in which the inspectors are employed by the state. FSIS also monitors processing plants for cleanliness and the avoidance of known hazards (such

as foreign matter in meat and poultry). The agency also oversees labeling; no statements or claims can be made on meat and poultry packaging that are not first approved by FSIS.

The Agricultural Marketing Service offers a voluntary but widely used grading program for meat and poultry, fruits and vegetables (both fresh and processed), milk and dairy products, and eggs. Only products with the top grade in each category are normally sold at retail. Producers pay for the grading inspections.

Food products other than meat and poultry are generally the responsibility of the FDA's Center for Food Safety and Applied Nutrition (CFSAN), which sets standards for products other than meat and poultry. Because, as of 2001, CFSAN employs fewer than eight hundred inspectors to monitor more than fifty thousand processing plants, it relies mainly on sampling and oversight of quality assurance systems to ensure product safety.

The federal agency with primary responsibility for seafood is the National Marine Fisheries Service (NMFS) of the National Oceanographic and Atmospheric Administration (NOAA) in the Department of Commerce. NMFS offers a voluntary seafood inspection program to the industry that allows products to carry the mark "Processed Under Federal Inspection" and/or a seal "U.S. Grade A." NMFS estimates that about 17 percent of the seafood consumed in the United States is certified under the auspices of the seafood inspection program.

FDA also regulates the labeling of food packages according to the name of the product, its ingredients, and nutritional value, among other information. It regulates the meaning of label terms such as "light" or "low-fat." Data developed or reviewed by the FDA and USDA provide the basis for the Nutrition Facts labels required on packaged food.

The Environmental Protection Agency sets tolerances for pesticide residues in or on food products or in animal feeds. These tolerance levels, which are set at very low levels, are enforced by CFSAN and FSIS through random sampling of food products and feed.

As a major player in the world food trade, the United States participates in Codex Alimentarius, the international body that fosters trade by creating widely recognized standards. The U.S. office of Codex is housed at the USDA's Food Safety and Inspection Service, and officials from FSIS, FDA, and EPA coordinate Codex activities for the U.S. government.

USDA's Food and Nutrition Service administers food assistance, programs intended to help the economically disadvantaged get more to eat and to understand better the importance of proper nutrition. The food stamp program is one of the nation's largest welfare programs, providing benefits to needy people to increase their food purchasing power. The Special Supplemental Nutrition Program for Women, Infants, and Children, known as WIC, provides nutritious food supplements and

nutrition counseling to pregnant women and to the mothers of infants and children up to five years of age. Low-income schoolchildren are provided with free or low-cost breakfast and lunch, and the milk program provides milk to children in schools and child-care institutions that do not have federally supported meal programs.

USDA's Center for Nutrition Policy and Promotion works with the Department of Health and Human Services to promote the Dietary Guidelines for Americans and the Food Guide Pyramid, which provides general advice on how much people should eat from the various food groups to achieve nutritional balance.

The Federal Trade Commission has the power to take action against false and misleading advertising of food as well as other products through an administrative action or by seeking a court injunction. It can also investigate mislabeled products not covered by other federal laws, such as milk jugs not filled as stated on the label.

Foods contaminated with pathogenic microorganisms or toxins pose a significant risk of illness and death in the United States. The Centers for Disease Control and Prevention (CDC) of the Department of Health and Human Services (HHS) investigates major outbreaks of food-borne illness and collects data on outbreaks from local and state health departments.

Foods imported into the United States are legally required to meet the same standards as those produced in the United States. As with domestic products, imports other than meat and poultry are regulated by the Food and Drug Administration, which can conduct product sampling to ensure that the foods meet health, safety, and labeling standards. Meat and poultry is regulated by the FSIS, which inspects processing plants in other countries to determine if they meet U.S. requirements. FSIS also determines whether the foreign country's inspection system is equivalent to that of the United States. Countries meeting those requirements can export food products to the United States, subject to quotas, tariffs, and other restrictions, and subject to inspection by U.S. officials upon arrival in the country.

Agents of the Department of Agriculture and the U.S. Customs Service enforce regulations on food items carried by travelers to the United States. Travelers are prohibited from bringing in fresh, dried, and canned meats and meat products from most foreign countries. Some fruits, vegetables, and plants may be brought into the United States without advance permission, but they must be declared, inspected, and found free of pests.

The United States is a major donor to international relief efforts. The U.S. Agency for International Development (USAID) operates the Food for Peace (FFP) program under Public Law 480. The agency donates commodities such as wheat, corn, rice, and soybean meal to private voluntary organizations, cooperatives, and international organizations, such as the United Nations World Food Program.

The Special Trade Representative (USTR) negotiates food trade agreements (along with non-food agreements) with foreign countries and, in so doing, relies on the expertise and information of the USDA's Foreign Agriculture Service (FAS). FAS also provides information on trade opportunities to U.S. exporters.

The U.S. government regulates food at virtually every stage of production, processing, and marketing. Federal programs in place since the 1930s encourage the production of food and fiber. Consumer issues, food safety most prominent among them, have been an important topic of federal regulation since the passage of the Pure Food and Drug Act in 1906 and have become even more important in recent years with the rise of consumer consciousness.

**GRAIN RESERVES.** Grain is the foundation of the world's diet. Since the beginning of agriculture, farmers have recognized the need to manage stocks of grain to prevent starvation in times of scarcity. In the Hebrew Bible, the Egyptians were directed to stockpile seven years of harvests in preparation for seven years of famine. In North America, early Indians overwintered grain reserves in woven baskets within pits dug into soil. Now, most grain is stored in metal bins or warehouses on or near the farms that produce the grain. Good sanitation is important, since significant grain losses may occur due to spoilage, rodents, and insects. The primary purpose of grain reserves is to help cope with food emergencies, but grain reserves are also used to stabilize grain prices and as a loan commodity.

#### Food Security

Food security in the fullest sense would mean that all people at all times have access to adequate quantities of safe and nutritious food. To ensure food security, many countries stockpile strategic grain reserves (SGRs). Grains are an easy-to-store and nutritious way to provide the basic needs of a population facing a food emergency until alternative food supplies can be arranged. Countries

with abundant supplies of grain will frequently sell or loan their stores of grain to countries without an adequate supply. SGRs are costly to establish and maintain. The United Nations Food and Agriculture Organization (FAO) and the World Bank recommend a grain reserve sufficient to cover three or four months' consumption, plus a cash reserve to import food. In the United States an SGR of up to 4 million metric tons of wheat, corn, sorghum, and rice is reserved for international humanitarian purposes.

Some countries—for example, India—are able to reserve large quantities of grain but lack the distribution system necessary to supply all areas of the country. In contrast, sometimes too much grain is reserved. In 1999 and 2000, China accumulated large stocks of low-quality grain at a time when consumers were demanding higher-quality grain. In response, China discarded its low-quality, low-value grain reserves.

Food emergencies can result from natural causes, such as pest outbreaks sparked by drought, floods, storms, earthquakes, or crop failures, as well as from war and terrorism. Due to advances in agricultural science, between 1950 and 1980 grainland productivity (yields per unit acre) and world cultivated acreage increased significantly, resulting in an abundance of world food. However, since 1980 the rate of food production increase has slowed, while population growth has continued to rise. Many countries are facing both population increases and shortages of resources that are important to agriculture—such as oil, topsoil, water, and undeveloped farmland.

### Stabilizing Grain Prices

In the United States, grain reserves have been used to protect farmers from wheat and feed grain production shortfalls and to provide a buffer against unusually sharp price movements. For example, under a farm commodity program administered by the USDA Consolidated Farm Service Agency (CFSA) in 2002, farmers place their grain in government-managed storage and receive an extended loan or advance deficiency payment against a target grain price.

### Ceres

Since 1930, atop the Chicago Board of Trade building, a 6-ton cast aluminum statue of Ceres has held a bag of corn in her right hand and a sheaf of wheat in her left. Ceres was created by sculptor John Storrs and is a symbol of the close association between the Chicago Board of Trade and agriculture. According to Roman mythology, Ceres (Demeter in Greek mythology) is the goddess of food grains and patroness of corn trade. She is associated with the ground from which crops spring, the bread produced from grain, and the work necessary to raise crops. Ceres presided over the distribution of grain to the urban poor. The word “cereals” is derived from her name.

**GRAPES AND GRAPE JUICE.** There is culinary potential in nearly every part of a grapevine: the skins (food coloring), the pulp and juice (jams, vinegars, wines, and brandies), the seeds (oil), the leaves (dolmas), and even the wood, which makes aromatic fuel for grilling and smoking.

In size, shape, color, flavor, texture, sweetness, acidity, astringency, and relative seed presence, the grape is almost infinitely variable. French ampelographer (vine expert) Pierre Galet counts more than 9,600 varieties among the nearly twenty million acres of grapes grown on all continents except Antarctica (Galet, 2000). And, although many older varieties have disappeared from commercial production, new varieties are constantly being created and tested by breeders.

Approximately 50 percent of all commercial vineyards are in Europe. Over half of all grapes are used for wine production. The rest are consumed fresh; canned; as raisins, jams, or juice; or distilled (Monette, 1988).

Grapes are unique in their ability to achieve Epicurean heights in an astonishing range of conditions: fresh, dry, unripe (sparkling wines like champagne), over-ripe (dessert wines like port), frozen (the vinous nectar *Eiswein*), evaporated and acidified (balsamic vinegar), slimed over with yeast (sherry), and even rotten with mold (another vinous nectar, *sauternes*).

No other fruit has reached so broadly or deeply into human culture as the grape. Art, history, psychology, medicine, politics, world trade, and religion are all infused with the imagery and substance of vineyards (John-

TABLE 1

Grapevine “family tree.”		
Genus and Species	Selected Varieties	Comments
(American) <i>Vitis</i> or <i>Muscadinia rotundifolia</i>	Scuppernong, Magnolia	The fruit and flavor of muscadines is virtually unknown outside the southeastern United States. Relatively low sugar, low acid, very thick skin, few large berries per bunch that ripens very unevenly. Fruity dessert wines are traditional, although some newly developed varieties have more neutral flavors and can be made into table wine.
(American) <i>Vitis aestivalis</i>	Norton, Lenoir	This is the American species most suited to dry table wine. The fruit is late-ripening but has high sugar, high acid, low pH, thick skin, unstable color, vinous flavor, and is always seeded. There are relatively few small berries per bunch
(American) <i>Vitis labrusca</i>	Catawba, Concord, Isabella, Niagara, Steuben. Note: these varieties may not be pure species	This species has relatively low sugar, low acid, low pH, soft pulp with thick skin, few moderate-size berries per bunch. Best suited for consumption fresh or as juice and jelly. Not suited for dry table wine, but can make pleasant sparkling, aperitif, and sweet fruity wines. Fruit flavors described as foxy or like passion fruit.
(American) <i>Vitis berlandieri</i> , <i>riparia</i> , and <i>rupestris</i>	Riparia Gloire, Rupestris du Lot, S04, 5 BB, 3309C, 110 R	These species are used mostly as phylloxera-resistant rootstocks to replace the tender roots of <i>V. vinifera</i> , but they are also in the parentage of European-American hybrids. <i>Riparia</i> berries are small, mostly black, contain high acid, and being early ripening can achieve fairly high sugar and herbaceous flavor.
(Eurasian) <i>Vitis vinifera</i>	Chasselas, Flame Seedless, Muscat blanc, Sangiovese, Sauvignon blanc, Syrah, Riesling	High sugar content, sometimes seedless, colors of many hues. Bunch and berry size is highly variable, but mostly better-filled bunches than American types. Table grapes that ship well, all types of wine grapes from mundane to sublime, and the best raisins.

son, 1989). Before the advent of modern medicine in the nineteenth century, unhealthy water was often rendered harmless and limbs saved from amputation by the antiseptic properties of wine. All forms and transformations of the grape enliven basic foods and are not only healthy but therapeutic.

### Grapes and Their Origins

Wild vines are common around the globe. In the family Vitaceae, there are more than a thousand species divided among sixteen living and two fossil genera, including *Ampelopsis*, *Parthenocissus* (both used for ornamental purposes), and *Vitis*, the “grapevine” genus. The French botanist J. P. de Tournefort first defined the genus *Vitis* in 1700, and it was one of the first plant genera studied by the great botanist Linnaeus (Galet, 1979). The word *vitis* means ‘vine’ or ‘centurion’s staff’ in Latin. It derives from the verb *viere*, meaning ‘to braid or weave together’, and is descriptive of climbing vines entwined with tree branches.

There are approximately sixty-five named *Vitis* species native to the temperate zones of Asia, Central America, and North America. A majority of the approximately two dozen North American species are found east of the Rocky Mountains. Unlike *Vitis vinifera*, which has a long (more than seven-thousand-year) history of cultivation, native American species remained largely in a wild

state until European colonists began to select among them for their fruit quality and disease resistance.

Grape seeds carry the embryo of genetic material from two parents, thus every seedling is genetically unique. Purposeful and natural crosses have led to improved varieties over time (Morton, 1985). As food, grape seeds are high in fatty acids yet low in their effect on blood cholesterol levels. With a high smoking point, grapeseed oil is the secret to truly French “French fries.”

As the source of food and drink, the grape is generally divided into two camps—the Eurasian (*Vitis vinifera*) and the North American (see Table 1).

### Sine Qua Non: American Roots for European Grapes

It was only after the phylloxera (plant louse) crisis in 1860s Europe that the roots of American vines became far more precious than their fruit, and hybridization became as important to the creation of new rootstocks as it had been to the creation of interesting new grape varieties. Technically speaking, a hybrid is the offspring of two individuals that differ by at least one gene and can be the progeny of crosses between varieties of the same or different species—and rarely of different genera, as is the case with *Vitis* × *Muscadinia* crosses. Hybrids between American and European types—for example, Foch,

The Temperance Movement raised the popularity of table grapes and especially of grape juice. It was even used by some churches for Communion wine. This circa 1904 brochure promotes grape juice from the Finger Lakes Region of New York, where viticulture was already well established. ROUGHWOOD COLLECTION.

Chambourcin, Seyval, and Vidal Blanc—can be good choices for vineyards where cold temperatures or fungal disease pressures make growing vinifera varieties difficult or uneconomical.

### Grape Juice

Raw grape juice, with help from passing yeasts, naturally ferments into wine first, then turns into vinegar. In fact, only timely and deliberate action prevents this from occurring. Pasteurization is the most common method for keeping grape juice from infusing itself with alcohol or acetic acid. American varieties make strongly flavored and deeply colored single-strength juice. By comparison, vinifera grapes would be quite insipid and cloying because of their high sugar content. This can be corrected by acidifying the grape juice with lemon juice, ascorbic acid, or tartaric acid. Most grape juices benefit from dilution with water or seltzer. Adding ginger ale to Concord grape juice creates the approved designated-driver libation “purple passion.” One would think that muscat varieties would make charming grape juice, but their special aromas and flavor do not survive the pasteurization process. (Cirami, 1996).

Grape juice is adept at transmutation. The juice of very unripe grapes, known as verjuice or green juice, is an acidic substitute for citrus called for occasionally for sauces or deglazing. Slightly unripe grape juice can be used for sparkling wine.

Highly acid but ripe grapes are the main ingredients for a potable grape foam produced in the French appellation of Crépy, just over the border with Switzerland. Fresh Chasselas must is put into a small stainless steel keg along with a few family-secret ingredients. By New Year’s, when the tap is opened, white foam will blast out

into waiting flutes. Consumption begins immediately, as it is considered bad luck to allow the foam to settle into a liquid of young wine.

Food writer Harry Nickles (1969) describes another use for grape juice—a sweetmeat made in a village near Sparta from fresh unfermented grape syrup (*epsima*) and flour. The process involves boiling the juice to reduce the volume and increase the sweetness, then adding the ashes of burned vine canes to clarify the juice as it settles. After decanting the sediment and straining, the liquid is further reduced by boiling. Finally, flour is added and the mixture is poured into a shallow pan where it cools into a chewy confection known as *grouta*.

In France fresh juice is boiled down into a syrup and simmered with other fruits to create a jam without sugar called *raisiné*.

### Dried Grapes

Dried grapes are known as sultanas or raisins (both seedless and seeded), and even as currants. They are found in recipes for many types of food—from meat stuffing to vegetarian couscous, from teetotaler baked goods to sauces and fruitcakes soaked in rum, port, or brandy.

Whereas it is generally fermented or distilled in Europe, grape sugar is particularly important in the cuisine of the Middle East. Sun-dried raisins are one form of portable grapes. Drying causes grapes to lose their water, but they retain their minerals, vitamins, fiber and about 324 calories per 100 grams. Another method of concentrating grapes for transporting is to repeatedly dip a string into grape juice and allow it to dry. Eventually many layers of dried grape juice will create sort of grape sugar candle.

Black Corinth or Zante (from the Ionian island of Zákynthos) currant grapes are a classic product of Greece. Without treatment with growth regulators such as gibberellin, the vines produce tiny, mostly seedless grapes, which make soft, tart little raisins that lend themselves to baked goods and stuffings.

Currants often join pine nuts and rice in a cocoon of grape leaves or dolmas. These leaves can be harvested any time in the growing season and briefly blanched before using. Or they can be found preserved in a saline and acid solution in glass jars at specialty shops. Generally speaking, the leaves of vinifera table grapes are ideal for this purpose, whereas the leathery and hairy-backed leaves of native American vines are not.

### Vines Beyond the Grape

Grapevines can provide welcome shade to patios. To avoid bees at the barbecue, however, one should consider planting male-rootstock varieties—such as Riparia Gloire or SO4—with large leaves (also good for dolmas) and no fruit. After the leaves have fallen, the canes from these patio vines can be woven into durable and functional wreaths and baskets for the kitchen. Chopped sections of grape canes can be stored in small paper bags for later addition to the smoker along with hickory or fruitwoods. The smoke has a strong flavor, so a little goes a long way.

**GRAVY.** The term "gravy" first appears in Middle English as *gravé* and is presumed to derive from French, since the word may be found in numerous medieval French cookbooks. The original medieval meaning was precise: the *gravé* consisted of the natural cooking juices that flowed from roasting meat. By implication, this meat was spit-roasted, and therefore two important implements were required to make and collect the gravy: a flesh fork for piercing the meat in order to increase the flow of drippings, and a dripping pan beneath the roast, designed to collect the gravy for use at table. Normally the gravy was skimmed of fat, salted, and then sent up as a sauce, although presalting was not necessary, since this could be accomplished to taste at table. The term in this sense has been replaced today by *jus*, as in beefsteak *au jus*.

The medieval roasted meat with *gravé* was generally served rare and not likely to have a counterpart in contemporary Byzantine cookery, since the Eastern Church forbade the consumption of blood or bloody food. Among Byzantine Christians, the gravy of pork, mutton, goat, and the mouflon of Cyprus (a species of wild goat prepared like venison) was often reduced over high heat and mixed with *garum* (fish sauce) or wine, as reported by several medieval travelers. The preparation was then served as a dipping sauce, since the meat was cut up into small pieces and eaten with a fork. The idea of treating gravy as a sauce base is extremely old and may in fact trace back to antiquity. The debate among purists as to whether gravy with additional ingredients constitutes a sauce has not been settled, and probably never will be.

With the revival of sauce cookery in seventeenth-century France, gravy underwent numerous sophistications with the addition of herbs, wine, and other highly flavored ingredients. The English custom of boiling mint or calendula blossoms with clear mutton gravy dates from this same period and was brought to colonial America. The most common addition to gravy, however, was drawn butter, which remained popular into the nineteenth century.

In his *Cooks and Confectioners Dictionary* (London, 1726), John Nott used the term "gravy" in several senses, including the meat stock or bouillon known as a "restaurant," or restorative. His recipe for Gravy Broth (served as a soup course) is typical of the period in its blurring of the distinctions between gravy, soup, and sauce:

Take a fleshy Piece of Beef, not fat, spit it and roast it; and, when it begins to roast, slash it with a Knife to make the Gravy run out, and keep it continually basting with what comes from it, mix'd with Claret; cut it often, and baste it 'till all the Gravy be come out, put this Gravy into a Sauce-pan over a few Coals; put some Salt, whole Spice, and Lemon-peel, and let it simmer: Put some Sippets in a Dish, pour in your Gravy, garnish your Dish with Oranges and Lemons, and serve it up.

Sippets were small triangular pieces of toasted bread, and the orange and lemon slices were placed around the

Dripping pan (Russian iron), stand (wrought iron), and basting spoon (wrought iron), some of the traditional implements for making gravy. All of the utensils are American and date from the 1790s. The pan was placed under a joint of meat turning on a spit so that the drippings could be collected and used as gravy. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

rim of the dish. The whole spices and lemon peel were strained out before the gravy broth was poured over the bread. The use of spices, vegetables, and other ingredients to heighten the flavor of gravy became common in English household cookery by the Victorian period. For example, in Eliza Acton's *Modern Cookery* (Philadelphia, 1848) adapted for the American market, there are fifteen recipes for gravy, most of them somewhat complex and more typical of what might be found in an urban rather than rural household.

In rural cookery of this period, it became common practice both in England and America to add flour or roux (cooked flour and fat) to gravy in order to thicken it. This was especially common for dishes served at breakfast or supper. Some period writers considered this an adulteration, while others treated it as an economical and practical way to extend the pan drippings. The Gravy for Chops, which appeared in *Cookery as It Should Be* (Philadelphia, 1855) is typical and resembles the type of gravy most Americans associate with the Victorian era:

Take out your chops when cooked; keep a large spoonful of fat in which they were cooked, in the pan;

dredge in as much flour as will make it a paste; rub this well together over the fire, until a light brown; then pour in as much boiling water as will reduce it to the thickness of cream, and add a tablespoonful of mushroom catsup and a little salt; let this simmer five minutes, and pour it through a sieve over the steak.

This type of quickly made gravy became popular in the United States as a fast food, especially after the Civil War, once iron cookstoves became a standard kitchen fixture. Milk was also commonly added to create a genre of white gravies as opposed to the common brown ones of the past. Chicken gravy over waffles, hashed beef gravy over fried potatoes, red bean gravy on ham, fried tomato gravy—the list of preparations is long with many, many regional variations. Easy to make, they became popular adjuncts to camp cookery and dishes prepared by men in hunting lodges, boat outings, and other outdoor activities.

The demand for convenience soon led to the development of commercial products imitating the homemade preparations. Thus we find prethickened gravies sold in cans, jars, and even in powder form to be reconstituted with boiling water. In America, the term has come to sig-

## TOMATO SOP

Slice firm, ripe tomatoes; roll in flour and fry in equal parts of lard and butter until brown on both sides. Remove several slices to a platter, stir those remaining with flour and small lumps of butter: then thicken with milk and season to taste. Sop with bread or toast.

FROM: C. Mac Sheridan, *The Stag Cook Book: Written for Men by Men* (New York: George H. Doran Co., 1922), 95.

nify any kind of homemade sauce, from the giblet gravy served with turkey at Thanksgiving, to tomato sauce made by Italian Americans for pasta. In this sense, the word “gravy” has been employed in advertising to imply that the commercial product tastes homemade. But one feature has never changed. Real homemade gravies always contain the essential juices of the thing being cooked, whether pan drippings from a pork chop or the juice that runs out of a tomato.

**GREECE, ANCIENT.** The appreciation of food in ancient Greece—by those who had the time and money—marks the beginning of what is known today as gastronomy. Greek literary texts (especially comic plays) of around 350 B.C.E. present detailed discussions of which foods were consumed, how much they cost, and how they would be prepared. From the same period one can trace the beginnings of the idea that each city would have its own local food specialities and its own distinctive wine. Adherents of the medical tradition begun by Hippocrates were developing dietary theories and compiling handbooks that dealt with the contribution made by individual foodstuffs to human health.

An interest in food and wine is evident in the oldest Greek literature. Alcman, lyric poet of Sparta, in a surviving verse fragment, lists five fine wines of the southern Peloponnese; in another, hot bean soup is jokingly demanded as payment for poetry. Hesiod’s *Works and Days*, a poem of farming and practical lore, tells of the hot June days when “goats are fattest and wine best and women lustiest and men weakest. . . . Then we need rocky shade and Bibline wine and creamy barley mash and the last milk of the goats, and the meat of a foraging cow that has not calved . . . and from an ever-flowing unpolluted spring to pour three of water and to make the fourth be wine” (*Works and Days*, lines 587–596). Many of the focal events in the two great Homeric epics, the *Iliad* and the *Odyssey*, take place around shared meals of roast meat and red wine. Odysseus’s description of the palace of Phaeacia is a reminder that fruit was prized and seasonal varieties had been developed: “Outside the yard is a big orchard on both sides of the gates . . . where tall trees spread their leaves, pears and pomegranates and shiny-fruited apples and sweet figs and leafy olives; their fruit never fails or falls short, winter or summer, all the year, but the West Wind, blowing, fertilises some and ripens others” (*Odyssey*, Book 7, lines 112–119). These texts were written before 600 B.C.E., and they set the scene for later gastronomy. Most notably, they also highlight olives (for olive oil) and wine. Archaeology shows that these two products already had been important in Greece for well over a thousand years: they remained essential components of the Greek diet throughout ancient times and are still so today. From prehistoric sites, including the Minoan palace at Knossos in Crete, there are vats and plentiful storage jars for oil and wine. From Classical times there are many fine paintings on cups and wine jars showing the olive and grape harvests, the marketing of oil, and the joys of wine. The god Dionysus, with his train of drunken male satyrs and ecstatic female maenads, features in many such paintings, as if to remind the viewer that wine and its pleasures are a divine gift.

In Greek terms any proper meal had three components, *sitos* (the staple: wheat bread or barley mash or one of the pulses), *opson* (the relish: fish, meat, vegetable, cheese, or just olive oil) and *oinos* (wine, the universal drink). The trouble with ancient Greek gourmets was that they were largely *opsophagoi*, “relish-eaters”: they put too much emphasis on fine fish and other relishes, and not enough on simple, wholesome bread. Even worse were the frequent meat-eaters, like the greedy god Heracles and the north Aegean peoples (Macedonians, Thracians, and Greeks of Thessaly), or excessive wine-drinkers—a “barbaric” habit reputed by many Greeks to have killed Alexander of Macedon in 323 B.C.E.

Barley grew well in Greece, but it did not make good bread; nor did emmer, the wheat species that grew best locally. Broths, porridges, and mashes were made with these. Athens and some other cities imported bread wheat from Sicily, North Africa, and the northern Black Sea

A *pithos* in the palace of Minos at Knossos, Crete. These pottery jars, often five feet tall, were designed to store grain, oil, and wine. Ropes were run through the lug handles on the sides so that a team of workers could move it to another location in the royal cellars. © ROGER WOOD/CORBIS.

coasts, and the Athenian market became famous for its fine industrially baked bread.

In Athens and many other Greek cities, fish was available at the market—expensive, as fine fish still is in Greece, but very fresh. Europe’s first gourmet writer, Archestratus (c.350 B.C.E.), wrote extensively on the types of fish that should be sought in specific cities, during which season, at what price, and the manner in which it should be cooked. “The bonito, in autumn when the Pleiades set, you can prepare in any way you please. . . . But here is the very best way for you to deal with this fish. You need fig leaves and oregano (not very much), no cheese, no nonsense. Just wrap it up nicely in fig leaves fastened with string, then hide it under hot ashes and keep a watch on the time: don’t overcook it. Get it from Byzantium, if you want it to be good. . . .” Some later readers knew Archestratus’s poem under the title *Gastronomia* (Rules for the stomach), the origin of our modern word “gastronomy.” A stone inscription dating to the third century found in the small city of Acraephia, not far north of Athens, sets out an official market price for over twenty kinds of fish, a sign of the close interest that governments took in this trade.

Meat was a different matter—expensive, like fish, but in short supply. Livestock was not, and will never be, abundant in much of Greece, owing to the mountainous topography and the consequent shortage of good pasture land. In addition, animals could not simply be killed but

needed to be sacrificed to a god. Meat was thus a relatively small part of the diet, a rarity enjoyed at city festivals (free to citizens), celebrations, family events (when participants spent as much as they could afford), and other special occasions. The sacrificial butcher-priest, the *mageiros*, who was always male, served also as cook on these occasions; the art of cookery was named for this profession, *mageirike technē* (sacrificer’s art).

Imported flavorings included *garos* (fish sauce), from the Black Sea coasts; *rous* (sumach, from Syria); and *silphion*, a now-extinct spice from North Africa, similar to asafetida. Coriander, cumin, and many other native aromatics were in use. Mastic, native to the island of Chios, was used to aromatize bread and spiced wine, and also as a natural chewing gum to freshen the breath. A rich source of information on classical Greek food is *The Deipnosophists* (Professors at dinner), written by the scholar Athenaeus around 200 C.E.

In the Classical period, the fifth and fourth centuries B.C.E., Greeks ate two meals a day: a lighter *ariston* (breakfast) late in the morning and a fuller *deipnon* (dinner) in the evening. Breakfast called for bread and olive oil, perhaps with fresh or dried fruit, and red wine. Dinner was a more serious matter, and might well be followed by a *symposion* (symposium, drinking party). Typically dinner consisted of two courses. The first was a selection of tasty small dishes, some of them resembling modern Greek *mezedes* (appetizers): shellfish, such as oysters, mussels, and clams, other seafood, salads and cooked vegetables, and fresh fruit. The main course might have included fine fresh fish dishes, delicacies such as sliced salted tuna, and perhaps meat. No wine was taken with dinner. A libation of neat (or undiluted) wine (offered to the gods and tasted by humans) marked the beginning of the symposium, with dried fruits and nuts, cakes perhaps flavored with sesame and saffron and drenched in honey, and plenty more wine, always diluted with water: how much water was a matter for endless discussion.

At both dinner and symposium the proper custom was to recline, a fashion that Greeks had learned from the Near East. At all meals at which guests might be present, men and women ate separately. At sacrifices and open-air meals they formed separate circles (but some religious ceremonies were for women only or for men only). At home only male diners used the *andron* (dining room), which literally means “men’s room.”

Conversation languished while the business of eating went forward. The symposium was the occasion for talk, both serious and lighthearted; it was also a time for composing and reciting poetry, and for music and dance performed by the participants or by hired artists (usually slaves), including the ubiquitous *auletrides* (flute-girls). These performers, along with other entertainers and *hetairai* (courtesans), breached the rule of separation of the sexes. Symposia might continue all night, drunkenness supervening slowly but surely, since one could not prop-

Greek *calyx krater* from the sixth century B.C.E. These vessels served as mixing bowls for wine and water and held about six to seven gallons. They were the focal point of the ancient Greek symposia, or drinking parties. COLLECTION OF THE METROPOLITAN MUSEUM OF ART. © BETTMANN/CORBIS.

erly refuse to drink; inhibitions disappeared. While some symposia turned into orgies, others formed the backdrop for some of the greatest intellectual achievements of Greece. A symposium just like those described here is the setting for the philosophical discussion of love that is recorded in Plato's *Symposium*.

Were symposia only enjoyed by an elite? This question is controversial, and the meager evidence can be read in more than one way. Certainly there were great differences in access to food between the rich, who could spend time on eating and entertainment and could have as much meat and fine fish as they wanted, and the very poor, who subsisted largely on pulses (chickpeas, fava beans, and others less nourishing), green vegetables, and roots and fruits (and maybe snails) gathered from the wild. In famine years, many citizens were reduced to such a diet.

**GREECE AND CRETE.** Greeks, until recently, have been mainly vegetarian not by choice but by necessity. In the mountainous Greek countryside it was not possible to pasture large herds and provide meat for everybody. In ancient times and even recently, meat was

a rare, festive dish, consumed on Sundays, at Easter and Christmas, and for important family feasts. The traditional Greek diet and the similar diet of the people of Crete—Greece’s largest island—are mainly based on regional and seasonal agricultural produce: vegetables, leafy greens (*horta*), various kinds of dandelion and chicory, mustard greens, both sweet and bitter, and amaranth shoots in the summer. The greens are either foraged from the hills and fields or cultivated. Grains, mainly in the form of homemade bread, were the basic staple, complemented with fruity olive oil, olives, beans and other legumes, local cheeses, yogurt, occasionally fresh or cured fish, and sometimes meat.

Typical dishes are vegetable stews—green beans, zucchini, artichokes, or leafy greens cooked in olive oil with onions or garlic and fresh or canned tomato or lemon juice during the winter. Tomatoes, zucchini, and eggplants are also stuffed with rice, sometimes with the addition of ground meat. Beans, chickpeas, and lentils are made into soups, while all seasonal vegetables and greens are also used to make the stuffing for pies wrapped in homemade or commercial phyllo pastry. *Hortopita* (greens pie), also called *spanakopita* (spinach pie), is probably the most common example. Lots of flat leaf parsley and the intensely fragrant dried wild oregano are the most common herbs used in Greek cooking. Celery, dill, and wild fennel are also used fresh, while mint is added to some dishes, fresh but also dried. Bay leaves flavor meat stews, and cinnamon is used in most tomato sauces and

meat stews, sometimes together with cloves. *Stifado* (rabbit, hare, or veal stew with pearl onions in red wine sauce) is scented with bay leaves, cinnamon, and cloves.

Only after the mid-1960s, as the country became more affluent, did meat gradually begin to play a significant role in people’s everyday diet. Around that time, the Greek demographic structure changed. At least four out of ten middle-aged Greeks who, in the early twenty-first century, lived in the big cities—Athens and Thessaloniki—came originally from agricultural areas. They moved with their families to the cities during the last forty years of the twentieth century, bringing with them the cooking and culinary habits practiced in the villages by their mothers and grandmothers.

Most people have kept their ancestors’ village homes and visit them on long weekends, summer holidays, and at Christmas and Easter. Many have also kept much of their land, so it is common for Greek families to produce the olive oil they consume—about forty pounds per person each year. And when they don’t produce it themselves, they buy it from friends who have a surplus. This reflects Greek society’s largely agricultural past. Olive oil is not just the primary fat used in Greek cooking, but is also basic to Greek people’s identity. It is tied to every ritual, both folk and religious, that marks the crucial events in the cycle of life. Priests anoint infants with olive oil when they are christened, and the bodies of the deceased are embalmed with olive oil and wine prior to burial.

Bread was the basic staple food up until the mid-1960s, as it used to be in ancient and Byzantine times. Although now they can afford a great variety of foods, Greeks still consume enormous quantities of bread. Traditional breads are often made with a combination of wheat, barley, and sometimes corn flour, using sour old-dough starter as leavening. Barley, easily growing in the dry and difficult climate of southern Greece and on the islands, was for many centuries the staple food of the ancients. It was ground and eaten as porridge or made into flat breads. Today in Crete and on the other islands, *paximadia* (rusks)—slices of twice baked and completely dry barley bread, which need to be briefly soaked in water to soften them—are still very popular. *Paximadia* keep well for many months and were the ideal food for sailors. They were only baked every two or three months, so they made good use of the oven heat, as wood was always in short supply in most arid Greek islands.

Lunch, eaten around 2 P.M., and dinner, eaten after 8:30 P.M. and often at 10:00 at night or even later, are the two principal meals of the day. Breakfast is usually just a cup of coffee, occasionally accompanied by a cookie or biscuit. Meals include a salad of fresh raw or blanched seasonal vegetables or greens, and end with seasonal fruits. Wine accompanies most meals. Greece has many old indigenous varieties of grapes that produce wonderful wines that have now started to be exported and appreciated by connoisseurs. Some of the best-known Greek grape varieties are *Xinomavro*, which produces the deep red wine of Macedonia; *Aigiorgitiko*, which produces

the red from Nemea in the Peloponnese; *Asyrtiko*, which produces a fruity white from the island of Santorini; and *Moschofilero*, which produces the fragrant fruity white from Mantinea in the central Peloponnese.

Sweets were originally part of the festive table, which almost always involves meat, usually lamb on most occasions. Now, of course, sweets tend to be eaten at all times of the day.

With its many islands, Greece probably has more boats per capita than cars. Nevertheless, fish and seafood have never been plentiful enough to become a staple for the people who live near the sea. The fish and seafood of the Aegean are exceptionally delicious but scarce, and the best fish that islanders manage to catch is sold to the big cities for much-needed cash. Red mullet, sea bream, grouper, mackerel, bonito, swordfish, smooth hound, sardines and anchovies, spiny lobster, octopus, calamari, catfish, and cockles are the most common of the many kinds of fish one can find in the market, especially in the winter.

The Venetians and Genoans, who ruled most of the country during the Middle Ages, and later the Ottoman Turks, who made Greece part of their empire and remained the rulers of northern Greece and Crete until the early 1900s, have all left their marks on Greek cooking. (The use of yogurt in cooking and baking, more prominent in Crete, is the result of the Ottoman influence.) But the rules of the Greek Orthodox Church are by far the most important element in shaping people's eating habits. Even nonreligious Greeks often abstain from

foods deriving from animals—meat, dairy products, and eggs—during the fast days that precede Easter, Christmas, and other religious occasions. It is notable that even the McDonald's restaurants in Greece serve special menus during those days. This is the reason that many traditional dishes, such as stuffed vegetables and phyllo-wrapped pies, come in two versions: one with meat (sometimes called the “festive”) or with cheese, and one without, for the fast days.

The numerous religious holidays are scattered throughout the year. These holidays have often evolved from ancient celebrations. Easter, Greece's most important feast, seems to have its roots in the pagan agricultural spring festivals of antiquity. Celebrated in the open country, amid fragrant herbs and multicolored flowers, the Easter table features tiny, succulent locally raised and fed spit-roasted lamb or kid and salads of wild greens, tender raw artichokes, and fresh fava beans. The traditional Easter sweets are made with *myzithra*, a generic name for the various regional creamy fresh sheep's milk cheeses of the season.

Many dishes are still closely related to religious holidays, although pizza and hamburgers, as well as *gyro* and the ubiquitous “Greek Salad” tend to banalize modern Greek food. *Magiritsa*, a delicious soup made from chopped lamb's innards, scallions, and dill, with a tart egg-and-lemon sauce, is only eaten after the midnight Resurrection Mass on Good Saturday. Pork is associated with the Christmas and New Year tables. Christmas has become a major holiday only during the past forty years. Pigs are raised by most families, especially on the islands, and are slaughtered in December to make sausages and other smoked or salted meats that are used as flavorings in vegetable or legume dishes throughout the year. At the festive table, one finds head cheese and stewed pork with winter vegetables such as celeriac and greens, often cooked with *avgolemono* (egg and lemon sauce). Ground pork is the stuffing for *labanodolmades* (cabbage leaves), the Christmas dish in Macedonia. Fish, a symbol of Christianity, is consumed on Annunciation Day (25 March), and always at the solemn meals that follow funerals.

Greek food follows the seasons. In the homes cooks do not make stuffed tomatoes or *melitzanosalata* (eggplant dip, made by mixing chopped grilled eggplant with garlic, olive oil, lemon, and parsley) in the winter, although these vegetables are now available all year round. The frugal Greek cooks ingeniously combine seasonal ingredients to create dishes that modern dieticians now use as

Greece is known as the land of olives, as the great variety found in any market will easily attest. Thirteen different types of olives are available at this stand in the Central Market in Thessaloniki in northern Greece. © JOHN HESELTINE/CORBIS.

models for the famed healthy Mediterranean Diet. This highly recommended diet was the result of a study by an American, Dr. Ancel Keys, and his associates, who compared the daily food intake and the overall health condition of the inhabitants of seven countries in the early 1960s. They found that the Greeks, and more specifically the inhabitants of Crete, fared best of all.

**GREEN REVOLUTION.** The Green Revolution was the notable increase in cereal-grains production in Mexico, India, Pakistan, the Philippines, and other developing countries in the 1960s and 1970s. This trend resulted from the introduction of hybrid strains of wheat, rice, and corn (maize) and the adoption of modern agricultural technologies, including irrigation and heavy doses of chemical fertilizer. The Green Revolution was launched by research establishments in Mexico and the Philippines that were funded by the governments of those nations, international donor organizations, and the U.S. government. Similar work is still being carried out by a network of institutes around the world.

The Green Revolution was based on years of painstaking scientific research, but when it was deployed in the field, it yielded dramatic results, nearly doubling wheat production in a few years. The extra food produced by the Green Revolution is generally considered to have averted famine in India and Pakistan; it also allowed many developing countries to keep up with the population growth that many observers had expected would outstrip food production. The leader of a Mexican research team, U.S. agronomist Norman Borlaug, was instrumental in introducing the new wheat to India and Pakistan and was awarded the Nobel Peace Prize in 1970.

Borlaug (b. 1914) was hired in 1944 to run a wheat-research program established by the Rockefeller

Foundation and the government of Mexico in an effort to make that country self-sufficient in the production and distribution of cereal grains. Borlaug's team developed varieties of wheat that grew well in various climatic conditions and benefited from heavy doses of chemical fertilizer, more so than the traditional plant varieties. Wheat yield per acre rose four-fold from 1944 to 1970. Mexico, which had previously had to import wheat, became a self-sufficient cereal-grain producer by 1956.

The key breakthrough in Mexico was the breeding of short-stemmed wheat that grew to lesser heights than other varieties. Whereas tall plants tend both to shade their neighbors from sunlight and topple over before harvesting, uniformly short stalks grow more evenly and are easier to harvest. The Mexican dwarf wheat was first released to farmers in 1961 and resulted in a doubling of the average yield. Borlaug described the twenty years from 1944 to 1964 as the "silent revolution" that set the stage for the more dramatic Green Revolution to follow.

In the 1960s, many observers felt that widespread famine was inevitable in the developing world and that the population would surpass the means of food production, with disastrous results in countries such as India. The United Nations Food and Agriculture Organization calculated that 56 percent of the human race lived in countries with an average per-capita food supply of 2,200 calories per day or less, which is barely at subsistence level (cited by Mann, p. 1038). Biologist Paul Ehrlich predicted in his 1968 bestseller *The Population Bomb* that "hundreds of millions" would starve to death in the 1970s and 1980s "in spite of any crash programs embarked upon" at the time he wrote his book (Ehrlich, p. xi).

In 1963, just such a devastating famine had threatened India and Pakistan. Borlaug went to the subcontinent to try to persuade governments to import the new varieties of wheat. Not until 1965 was Borlaug able to overcome resistance to the relatively unfamiliar crop and its foreign seeds and bring in hundreds of tons of seed to jump-start production. The new plants caught on rapidly. By the 1969–1970 crop season—about the time Ehrlich was dismissing "crash programs"—55 percent of the 35 million acres of wheat in Pakistan and 35 percent of India's 35 million acres of wheat were sown with the Mexican dwarf varieties or varieties derived from them. New production technologies were also introduced, such as a greater reliance on chemical fertilizer and pesticides and the drilling of thousands of wells for controlled irrigation. Government policies that encouraged these new styles of production provided loans that helped farmers adopt it.

Wheat production in Pakistan nearly doubled in five years, going from 4.6 million tons in 1965 (a record at the time) to 8.4 million tons in 1970. India went from 12.3 million tons of wheat in 1965 to 20 million tons in

Norman Borlaug, the acknowledged “father” of the Green Revolution. © AP/WIDE WORLD PHOTOS.

1970. Both nations were self-sufficient in cereal production by 1974.

As important as the wheat program was, however, rice remains the world’s most important food crop, providing 35–80 percent of the calories consumed by people in Asia. The International Rice Research Institute in the Philippines was founded in 1960 and was funded by the Ford and Rockefeller Foundations, the government of the Philippines, and the U.S. Agency for International Development. This organization was to do for rice what the Mexican program had done for wheat. Scientists addressed the problem of intermittent flooding of rice paddies by developing strains of rice that would thrive even when submerged in three feet of water. The new varieties produced five times as much rice as the traditional deepwater varieties and opened flood-prone land to rice cultivation. Other varieties were dwarf (for the same reasons as the wheat), or more disease-resistant, or more suited to tropical climates. Scientists crossed thirty-eight different breeds of rice to create IR8, which doubled yields and became known as “miracle rice.” IR8 served as the catalyst for what became known as the Green Revolution. By the end of the twentieth century, more than 60 percent of the world’s rice fields were

planted with varieties developed by research institutes and related developers. A pest-resistant variety known as IR36 was planted on nearly 28 million acres, a record amount for a single food-plant variety.

In addition to Mexico, Pakistan, India, and the Philippines, countries benefiting from the Green Revolution included Afghanistan, Sri Lanka, China, Indonesia, Iran, Kenya, Malaya, Morocco, Thailand, Tunisia, and Turkey. The Green Revolution contributed to the overall economic growth of these nations by increasing the incomes of farmers (who were then able to afford tractors and other modern equipment), the use of electrical energy, and consumer goods, thus increasing the pace and volume of trade and commerce.

As successful as the Green Revolution was, the wholesale transfer of technology to the developing world had its critics. Some objected to the use of chemical fertilizer, which augmented or replaced animal manure or mineral fertilizer. Others objected to the use of pesticides, some of which are believed to be persistent in the environment. The use of irrigation was also criticized, as it often required drilling wells and tapping underground water sources, as was the encouragement of farming in areas formerly considered marginal, such as flood-prone regions in Bangladesh. The very fact that the new crop varieties were developed with foreign support caused some critics to label the entire program imperialistic. Critics also argued that the Green Revolution primarily benefited large farm operations that could more easily obtain fertilizer, pesticides, and modern equipment, and that it helped displace poorer farmers from the land, driving them into urban slums. Critics also pointed out that the heavy use of fertilizer and irrigation causes long-term degradation of the soil.

Proponents of the Green Revolution argued that it contributed to environmental preservation because it improved the productivity of land already in agricultural production and thus saved millions of acres that would otherwise have been put into agricultural use. It is estimated that if cropland productivity had not tripled in the second half of the twentieth century, it would have been necessary to clear half of the world’s remaining forestland for conversion to agriculture (Brown, *Eco-Economy*).

However, the rates at which production increased in the early years of the program could not continue indefinitely, which caused some to question the “sustainability” of the new style. For example, rice yields per acre in South Korea grew nearly 60 percent from 1961 to 1977, but only 1 percent from 1977 to 2000 (Brown et al., *State of the World 2001*, p. 51). Rice production in Asia as a whole grew an average of 3.2 percent per year from 1967 to 1984 but only 1.5 percent per year from 1984 to 1996 (Dawe, p. 948). Some of the leveling-off of yields stemmed from natural limits on plant growth, but economics also played a role. For example, as rice harvests increased, prices fell, thus discouraging more aggressive production. Also, population growth in Asia slowed, thus

reducing the rate of growth of the demand for rice. In addition, incomes rose, which prompted people to eat less rice and more of other types of food.

The success of the Green Revolution also depended on the fact that many of the host countries—such as Mexico, India, Pakistan, the Philippines, and China—had relatively stable governments and fairly well-developed infrastructures. These factors permitted these countries to diffuse both the new seeds and technology and to bring the products to market in an effective manner. The challenges were far more difficult in places such as Africa, where governments were unstable and roads and water resources were less developed. For example, in mid-1990s Mozambique, improved corn grew well in the northern part of the country, but civil unrest and an inadequate transportation system left much of the harvest to rot (Mann, p. 1038). According to the report by David Gately, with the exception of a few countries such as Kenya, where corn yields quadrupled in the 1970s, Africa benefited far less from the Green Revolution than Asian countries and is still threatened periodically with famine.

The Green Revolution could not have been launched without the scientific work done at the research institutes in Mexico and the Philippines. The two original institutes have given rise to an international network of research establishments dedicated to agricultural improvement, technology transfer, and the development of agricultural resources, including trained personnel, in the developing countries. A total of sixteen autonomous centers form the Consultative Group on International Agricultural Research (CGIAR), which operates under the direction of the World Bank. These centers address issues concerning tropical agriculture, dry-area farming, corn, potatoes, wheat, rice, livestock, forestry, and aquatic resources, among others.

Future advances in agricultural productivity depend on the development of new varieties of plants such as sorghum and millet, which are mainstays in African countries and other less-developed areas, and on the introduction of appropriate agricultural technology. This will probably include biotechnology—the genetic alteration of food plants to give them desirable characteristics. For example, farmers in Africa are plagued by hardy, invasive weeds that can quickly overrun a cultivated plot and compel the farmer to abandon it and move on to virgin land. If the plot were planted with corn, soybeans, or other crops that are genetically altered to resist herbicide, then the farmer could more easily control the weeds and harvest a successful crop. Scientists are also developing a genetically modified strain of rice fortified with vitamin A that is intended to help ward off blindness in children, which will be especially useful in developing countries. While people have expressed concern about the environmental impact of genetically modified food plants, such plants are well established in the United States and some other countries and are likely to catch on in the developing world as well.

**GREENHOUSE HORTICULTURE.** Plant cultivation is influenced by various factors, such as soil quality, water availability, and climatic conditions. Techniques have been developed either to adapt food crops to their environment (as by breeding and selecting plants more resistant to drought or with shorter production cycles), or to adjust the environment (for example, temperature, nutrient supply) to meet plant needs. Practical means of modifying the environment surrounding the plants have involved methods such as the use of windbreaks, mulches, plant or row covers, and cold frames. These methods of protecting plants may be described as passive methods since they only raise barriers between the plants and their environment, and do not control the environment. Some types of garden frames (hotbeds, heated frames) may be heated by artificial means, but do not actually provide for any control of the environment.

The only method of food crop production that makes use of control of the environment is greenhouse production. Modern greenhouse production is also referred to as controlled environment agriculture (CEA). With the use of a greenhouse, it is possible to cultivate food-producing plants in locations and at times when climatic conditions would adversely affect them or even prevent them from growing. Also, when climatic conditions allow outdoor plant cultivation, greenhouses can be used to protect crops against weather phenomena (such as wind, excessive rain, or hail) that would negatively affect them. For the purpose of this article, the term “greenhouse” is defined as a structure covered with a transparent or translucent material, in which environmental conditions can be modified or controlled, for the cultivation of plants. Tunnels are also used to modify environmental conditions for plant production, but are not usually considered greenhouses. Since the distinction between greenhouses and tunnels is not always clear in the literature, both structures, when high enough for people to move and work freely in them, will be considered together.

### **Food Produced in Greenhouses**

Although greenhouses have been in existence since 1800 (or earlier), and greenhouse food production started to develop as an industry in the second half of the nineteenth century, the largest growth and expansion of the greenhouse industry occurred throughout the world following World War II. Today, food production in greenhouses can be found in all continents. Most popular food crops grown in greenhouses are tomato (beefsteak, cluster, Italian, cherry), cucumber, and sweet pepper. Other greenhouse grown vegetables include watermelon, muskmelon, summer squash, zucchini, lettuce, eggplant, snap beans, celery, cabbage, radish, Welsh onion, and asparagus. Fruits such as grapes, strawberry, banana, pineapple, papaya, orange, mandarin, cherry, and fig, as well as culinary and medicinal herbs, are also grown in greenhouses.

### **Today's Greenhouses**

**Covering materials.** The main greenhouse covering materials are glass and polyethylene (PE). Glass has been used since the early days of greenhouses. The introduction of PE film after World War II was the main reason for the expansion of greenhouse production around the world, and it is now the most widely used covering material in the world. Glass-covered greenhouses are concentrated mainly in northern Europe and North America. The low cost of the PE greenhouse is the main reason for its high popularity, especially in developing countries. In recent years, the use of PE-greenhouses has even spread to northern regions. Research has shown that, under Canadian climatic conditions, heating costs of a double-layer PE-greenhouse are 20 to 30 percent lower than for a glass-covered greenhouse. Most of the greenhouses built now in Canada are covered with PE. Stan-

dard PE film blocks the ultraviolet, but not the infrared radiation, and has a short durability. However, improved PE films retain the infrared, but allow the ultraviolet, radiation (necessary for the bees, used for pollination of plants, to orient themselves) in the greenhouse, and are more durable. Polyvinyl chloride (PVC), another plastic film used to cover greenhouses, is used mostly in Japan. Other covering materials for greenhouses include rigid plastic acrylic, fiberglass, polycarbonate, and PVC panels, but their use is generally limited because of their high cost, compared to PE. Beside glass and PE, polycarbonate is often used on the sidewalls of polyethylene greenhouses in northern regions because of its good insulation, durability, and reasonable cost.

**Technology in the greenhouse.** Greenhouses come in many styles and sizes, from the original houses with minimal climate control (furnace and vents) to the modern 10-ha (25-acre) or more, multispan greenhouses with high-tech climate controls (sophisticated and powerful heating system, CO<sub>2</sub> enrichment, evaporative cooling pads, exhaust fans, roof vents, thermal/shade curtain, computer controls, light sensors). Most sophisticated greenhouses are generally found in the developed, northern countries. Phytotrons are highly sophisticated structures that allow for accurate control of environmental conditions including light, and are generally used for scientific research in universities and research institutes. However, phytotrons cannot be considered greenhouses since they are not covered with a transparent material.

The degree of environment control needed depends on various factors. The first factor is the location of the greenhouse (local climatic conditions). Northern regions are characterized by cold winters and warm summers. If the objective is to grow plants all year long, then such large differences in climatic conditions between winter and summer require a high-tech greenhouse. In regions such as the Mediterranean (Spain, Italy, Morocco, Greece), the mild winter climate does not require the use of powerful heating systems, and low-tech greenhouses are sufficient for winter production. However, these regions have very hot summers, and the use of a low-tech greenhouse may not provide satisfactory temperature control to grow plants during summertime.

The production schedule also affects the level of environment control and thus the level of technology. A greenhouse in northern regions may require a high level of climate control if the objective is to grow crops all year long (or long-season crops). If the objective is only to extend the production season (e.g., one early crop in spring), then a less sophisticated greenhouse could be satisfactory.

Optimal growing conditions differ from one species to another. For example, lettuce prefers cooler temperatures than cucumber. Thus, the crop grown in the greenhouse may influence the level of environment control needed or desired. A low-tech greenhouse may provide

TABLE 1

<sup>w</sup> These regions include the following countries (in order of importance of their greenhouse industry): Western North Africa: Morocco, Algeria, Tunisia; Eastern North Africa: Libya, Egypt; Middle East: Jordan, Lebanon, Syria; Arabic peninsula: Saudi Arabia, Kuwait, United Arab Emirates, Iraq, Bahrain, Qatar.

sufficient climate control for lettuce but not for cucumber, depending on the location of the greenhouse and the production schedule.

Economic development also plays a role in the level of technology used in the greenhouse. In developing countries, growers may not be able to afford the most sophisticated equipment, and may lack technical expertise and technical support.

**Greenhouses in desert regions.** Although greenhouses were developed in northern regions as a means of protecting crops against cold temperatures, and are therefore generally associated with cold climates, they are also used in arid regions such as Saudi Arabia. In such regions, the objective of the greenhouse is to protect plants from the excessive solar radiation and temperature, and to prevent excessive water loss by plants (especially since water resources are generally limited in those regions). Therefore, technology in greenhouses in these regions is directed toward cooling.

**Artificial lighting.** In northern countries, high-tech greenhouses can provide optimal growing conditions (temperature, humidity, carbon dioxide) for vegetable crops even during the coldest winter months. However, even with excellent climate control, yield and quality of crops grown during these months are low due to the low light level available. Research has shown that it is possible to produce good yield of high-quality produce during

the winter months by using artificial light to supplement the natural radiation. The most common artificial lighting is the high-pressure sodium lamp. The high cost of electric energy in many regions is the most important factor preventing an increased use of artificial light.

## Production Systems

**Growing in soil.** Since the early days of greenhouses, plants have been grown in soil or in soil-filled containers. The first technique for fertilizing plants, which is still in use today in organic production, was the use of manure. Today, fertilization of plants can also be accomplished by incorporating chemical fertilizers in the soil, or by distributing fertilizers dissolved in water (so-called fertigation) to plants with a drip (trickle) irrigation system. Intensive and repetitive cultivation of crops on the same soil generally results in a degradation of soil properties and fertility. Salt accumulation may be another problem in soil cultivation. Incorporation of manure, compost, and other organic materials into soil can be used to improve its structure and replenish its fertility. However, ensuring perfect fertilization of plants grown in soil is still a difficult task. Furthermore, intensive and repetitive cultivation of crops on the same soil can also result in insect or disease infestation. Soil replacement and soil fumigation are two solutions, but the first technique is expensive and the second is not always successful. Greenhouse production in soil is still used widely.

TABLE 2

**Estimated area (ha) of protected crops per region and type of structure**

	Greenhouses + Tunnels		Total
	Plastic	Glass	
Asia	440 000	3 000	443 000
Mediterranean	97 000	8 000	105 000
Americas	15 600	4 000	19 600

Total	586 300	40 800	627 100

\*Excludes European countries on the Mediterranean Sea.

**Growing without Soil**

In order to better control fertilization for optimizing plant growth and yield, and also to avoid the problems occurring in soil, growing systems that do not use soil (soilless) were developed for the cultivation of greenhouse crops. These soilless systems can be classified in two groups: liquid (water) and solid (artificial substrates that are either inorganic or organic). Systems using water as a growing medium are the nutrient film technique (NFT), deep flow technique (DFT), and aeroponics. Common inorganic media are rockwool, vermiculite, perlite, and clay pellets. Organic substrates are peat, coconut coir, sawdust, and straw. Inorganic and organic substrates are usually contained in bags, and plants are irrigated with a complete nutrient solution distributed by a drip irrigation system. The excess of nutrient solution can either be allowed to leak into the ground or is recuperated and recirculated (after treatment) to plants. In liquid systems, plant roots are continuously exposed to nutrient solution, which is not leaked into the ground.

Growing methods using artificial substrates or water are known as soilless culture or hydroponics. Hydroponics is literally defined as the growing of plants in water, but the plants are actually grown in a complete nutrient solution. Ideally, the term *hydroponics* should be reserved for water culture, and the term *soilless culture* for plant cultivation on artificial substrates. In practice, the terms *hydroponics* and *soilless culture* are used indiscriminately to describe water and substrate-based systems.

Although official statistics are unavailable, hydroponic systems are known to be used extensively for food production in greenhouses. The most popular soilless medium for hydroponic vegetable production is rockwool. The nutrient film technique is also often used, but to a much lesser extent than rockwool. In some regions, the availability of low-cost materials may provide alternative substrates. For example, in British Columbia, sawdust, a residue of the large forestry industry, is commonly used as a substrate. Both aeroponics and DFT remain in little use today.

**Insect and Disease Control in Greenhouses**

One objective of hydroponics is to avoid insects and diseases that may occur in soil. In a soilless culture system, such as rockwool, it is easy to remove infected plants. However, spread of diseases can occur very quickly in systems where nutrient solution is recirculated. Methods such as filtration of the nutrient solution, and disinfection with ozone or ultraviolet light, have been developed to eliminate pathogens that may be present in the nutrient solution. However, these methods are often expensive and not completely effective.

Greenhouses are used to create and maintain an environment ideal for plants. However, this environment is often favorable for insects and pathogens too. In the past, the control of insects and diseases in greenhouses was accomplished with the use of pesticides, but over time both insects and diseases have developed resistance to such pesticides, while consumers have begun to demand pesticide-free produce. Biological agents are now used to control whitefly, thrips, aphids, and two-spotted spider mite in greenhouses; few reliable biological agents are currently available for the control of diseases.

**Research on Greenhouse Food Crops**

In countries or regions where greenhouse production is an important industry, government and universities are generally involved in research on greenhouse production. The general objective of the research is to improve yield and quality of produce and profitability of production, by investigating all aspects of greenhouse production: greenhouse design and covering materials, growing methods, environment controls, substrates, plant nutrition, plant pathology, and insect control. Grower associations may also be involved in the development of research priorities, and may contribute financially to the expenses of research.

Due to the presence of a large and technologically advanced greenhouse industry in the Netherlands, the most notable research institutions are found there. The Research Station for Floriculture and Glasshouse Vegetables (under the Ministry of Agriculture, Nature Conservancy and Fisheries) has five sites. The other important Dutch institution is the University of Wageningen.

In the United Kingdom, Horticulture Research International (HRI), the largest horticultural research establishment in the world, maintains an active research program on greenhouse crops and provides its services (from fundamental research to technology transfer) to research councils, government departments, growers, and commercial industries, in the European Community (EC) and other countries.

In the Americas, the Greenhouse and Processing Crops Research Centre (GPCRC; Agriculture and Agri-Food Canada) is the largest research facility specializing in greenhouse vegetables. The GPCRC is a leading mem-

Organically grown greenhouse grapes at the Henry Doubleday Research Association's headquarters in Ryton, England, near Coventry. During the Roman period, England's climate was considerably warmer, and grapes could be cultivated into the Midlands. Today, grapes can be grown only in Kent, in southeastern England; otherwise, table and wine grapes must be raised under glass. © MICHAEL BOYS/CORBIS.

ber of the Canadian Network for Greenhouse Vegetable Research.

Japan, Spain, and Israel are some of the other countries with important research programs in horticulture, including greenhouse food production.

The International Society for Horticultural Science (ISHS) is an international organization of horticultural scientists, which aims at promoting research in all branches of horticulture, including greenhouse food production. Within the ISHS, there are various commissions and working groups related to greenhouse production.

### Future of Greenhouse Food Production

As the world population continues to increase, and more agricultural land is lost to urban development, intensive food production in greenhouses may play a more impor-

tant role in food production. Furthermore, improving economic conditions in developing countries and an increasing preoccupation with health and nutrition will increase demand for high-quality food products. Through controlled climate and reduced pesticide use, greenhouses can meet this consumer demand. Foods with improved health characteristics or containing nutraceuticals (substances with pharmaceutical or health-beneficial properties that can be extracted or purified from plants) can be grown pesticide-free in greenhouses.

**GRILLING.** Grilling is a fast, dry method of cooking tender cuts of meat and vegetables with radiant heat directed from below or from above. Its chief benefit is that it provides for the maximum amount of browning. In addition, a well-seasoned grill imparts a distinct flavor of its own to food cooked on it.

Virtually every American man either feels himself to be a master of outdoor grilling or experiences a twinge of guilt at falling short. The backyard barbecue has become for many the epitome of the suburban good life.

Grilling owes part of its appeal to its apparent simplicity: humans, fire, and meat. But many people are deceived by what looks like a simple process, and a lot of good food ends up ruined unnecessarily. Worse yet, some of the most delicious uses of the outdoor grill are ignored.

It is important to understand that grilling is not the same as barbecuing, even though both can be done on the same covered grill wheeled out of the garage on Sunday afternoons. Barbecue is an indirect slow-cooking process that uses long periods of exposure to low heat to tenderize tough cuts like brisket and chuck steak. It is generally agreed that the correct barbecue temperatures

are from 180°F to 300°F. During the hours of cooking, extra flavor can be imparted from the smoky character of the grill, from the fuel used, and from sauces that are applied regularly. It is possible to get and satisfy a sudden impulse to grill. Barbecue, on the other hand, is a matter that requires planning, careful thought, and the provision of some form of amusement for the chef.

### Methods of Grilling

Grilling can be divided into three major cooking styles, depending on how the heat source is configured. But all agree that the heat used must be above 500°F. The under-heat technique and grill roasting have the advantage of flavor enhancement from the grill itself; other methods only simulate some of the attributes of grilling.

In traditional or under-heat grilling, food is placed on a rack or grill bars over a gas or charcoal grill. Because of the fast nature of the cooking process, it is necessary to preheat the grill and the racks.

In top-heat grilling or broiling, used mostly in restaurants, the food is placed under a salamander, a professional overhead cooking oven. Again the grill (broiler) must be preheated, for quick searing. The process does produce a fine grill quality, but falls short in two areas. It does not leave the distinct grill marks so prized by many chefs and grill fanatics alike, and it also does not impart a smoke flavor.

Pan grilling, the third main method, is suitable for the most tender cuts. The food is cooked directly on a heavy cast-iron pan or ridged griddle pan. The cooking surface should be lightly seasoned to avoid sticking. One advantage of this method is that the food can be seared on a ridged pan, then finished in the preheated oven. This professional method is practical when preparing banquet menus, because the chef can be sure of consistently cooking to the same degree of doneness.

**Other techniques.** Grill roasting or indirect grilling is a hybrid technique. The procedure uses a conventional grill in a nontraditional way: fire is ignited under part of the grill, the food is placed over the unheated or coolest part of the grill, and the grill lid is closed. Some of the flavor of the grill is imparted to the food, which is usually browned over the heated part. Grill roasting is best for foods that are already tender but have a larger mass; birds and fish are good candidates.

Grill smoking is another variation on indirect grilling. Before you start to grill, place a metal dish or foil package containing moistened wood chips or herbs below the grill and over the fire. The heat will make lots of smoke that will fill the closed grill and flavor the food. This is a particularly good technique to use with brined foods.

### Grilling Basics

In terms of grilling tips, simple common sense is the rule. Always trim excessive fat off meat; this will help stop flare-

Grilling is a popular method of cooking for outdoor meals, especially during the summer. Entire menus can be created from grilled vegetables, meats, and fish. There is also a shift in the gender of the cooks, since grilling is commonly perceived as a male task. PHOTO BY ANDRÉ BARANOWSKI.

up, which adds a combustion taste to grilled foods. Always remove silver skin and connective tissue; silver skin does not dissolve when cooking, and connective tissue can cause meat to warp on the grill as the elastin shrinks.

As is true with all high-heat cooking, the best results come from food of uniform thickness. Trim the tapered ends from chicken breasts and vegetables and cook separately or reserve for another use. If grilling a vegetable—asparagus, for instance—try to select pieces that are of uniform thickness. Cutting other vegetables on a mandoline—a compact, hand-operated wood- or stainless steel-frame slicing and cutting machine with various adjustable blades—makes uniform thickness easy to obtain.

Dry ingredients that are exposed to high heat brown, their protein transformed by a series of changes called the Maillard reactions. Browned meats are much more flavorful, and when people say that they love the smell of cooked meat, they are in fact admiring the aromas that accompany browning. Maillard reactions take place only at temperatures well above the boiling point of water, so it is essential to pat meat that is wet or marinated dry before grilling. Meat and vegetables can also be brushed with oil or rubbed with infused oil. This actually facili-

tates browning while it adds flavor and prevents items from sticking to grids.

Season at the last minute. Never (except when braising) let meat sit in a coat of salt. Instead, add salt or salt-and-spice mixtures immediately before cooking. If salt is left on the surface it draws out the juices and toughens the meat. Be careful not to burn spices. With dry herb-and-spice rubs used to impart flavor, brush off excess before grilling; an option is to brush over the surface with oil before cooking, to prevent burning dry-rub ingredients.

When using natural fuel (charcoal) make sure coals are the correct temperature, and burnt down. A two-second hand count (meaning you can't hold your hand over the grill for more than two seconds) is the rule for a grill between 450°F and 500°F. Nothing imparts a bad resin flavor like charcoal that is not fully ignited and a cool grill.

### The Science of Grilling

Some understanding of cooking chemistry helps in grilling. Chefs are reexamining the use of brining or salting to produce juicy items today, and it is only a matter of time before the consumer catches on to this technique.

Brining—soaking lean cuts in salted water—preserves moisture. For fish, pork, chicken, or shrimp, prepare a brine with one cup of kosher salt per gallon of water (some brines also call for a small amount of sugar). Soak chicken in brine for two to twenty-four hours, other foods for as little as an hour. Rinse well, pat dry, and use the indirect method described above. The science behind the brine is simple; meat proteins are made up of amino acids, some of which are highly charged. They interact with the salt ions in the brine to open their structure and to dramatically increase their water-holding capacity. The salt actually moves into the meat, and extra water is also absorbed; on the grill, the salt in the meat holds on to the moisture, and so does the protein. The result is a juicier product, even from the high heat of the grill or the medium-high heat of grill roasting. Another way to impart flavor is by use of marinades and basting. Before cooking, meat proteins and vegetables may be marinated in mixtures of oil with vinegar, wine or citrus juice, herbs and spices, and other ingredients to help tenderize and add flavor. Marinades should always be blotted dry before grilling.

The process of grilling must also be defined in terms of the fuel used. There are several different types of grills, but gas and charcoal are by far the most common. They are also the source of the great grill debate: efficiency versus flavor. Today, gas grills represent about 60 percent of sales to household consumers. It is clear that they have their advantages, the most touted being ease of use, not having to add more fuel during long cookouts, and a juicy end product. Grilling purists, however, argue that hardwood charcoal gives a better flavor, and a smoky, drier character. The fuel source for charcoal grills has been recognized for at least five thousand years. No one is certain who discovered charcoal, but evidence of early use has been found all over the world. What most consumers may not know is that charcoal is actually wood; it is created by heating wood to high temperatures. Charcoal does provide a distinctive flavor that is not easily reproduced. And with the use of hardwoods like hickory, cherry, and mesquite, the flavor profile of the final product may have infinite variety. It is a tough decision for many people: the convenience of a gas grill against the flavor of charcoal.

**GRIMOD DE LA REYNIÈRE.** Named Alexandre-Balthazar-Laurent by an aristocratic mother and a farmer father, Grimod de la Reynière (1758–1837) was a rich eccentric with extravagant ways. He began a career as a theater critic but became one of the first to develop French gastronomic literature through the eight volumes of his *L'Almanach des gourmands*, which he published from 1803 to 1812. He originated the double genre of food critic and restaurant guide, providing practical information as well as critical standards. These were formulated by his jury of tasters, twelve friends who met weekly at the five-hour dinners he staged in his Paris home.

In 1808 his *Manuel des amphitryons*, a condensation of the material of the almanac, established the idea that the consuming public wanted guidance from an authoritative judge. The application of judge and jury to table matters was appropriate to the chaos of post-Revolutionary Paris and to the beginning of public restaurants during the transition from “ancient” to modern French cuisine. Such autocratic judgment created enemies and, forced to leave Paris in 1812, La Reynière sent out a public notice of his death and staged a funeral banquet in order to predict, accurately as it turned out, how very few friends would attend. He spent the rest of his life in retirement in the countryside, married to the actress who had been his mistress.

La Reynière’s influence in creating a critical guide for bourgeois consumers and gastronomes in the newly de-

Grimod’s fondness for the flesh of game and that of actresses is evident in this fanciful recipe:

“Stuff an olive with capers and anchovies and put it in a garden warbler. Put the garden warbler in an ortolan, the ortolan in a lark, the lark in a thrush, the thrush in a quail, the quail in a larded lapwing, the lapwing in a plover, the plover in a red-legged partridge, the partridge in a woodcock—as tender as Mlle Volnais, the woodcock in a teal, the teal in a guinea fowl, the guinea fowl in a duck, the duck in a fattened pullet—as white as Mlle Belmont, as fleshy as Mlle Vienne, and as fat as Mlle Contat, the pullet in a pheasant, the pheasant in a duck, the duck in a turkey—white and fat like Mlle Arsène, and finally, the turkey in a bustard.”

—*Larousse Gastronomique*, p. 532

“The local wine, a dinner at your friends’ house, and music performed by amateurs are three things to be equally dreaded.”

—*Larousse Gastronomique*, p. 531

mocratized theaters of the table, in houses and in restaurants, extends to this day. While the prose and outlook of his contemporary gastronome, Brillat-Savarin, were more humane, Grimod's delight in staging dining scenes that were theatrically absurd and macabre, a sort of *cuisine noire* (black-comedy cuisine), is peculiarly modern.

**HALLOWEEN.** Halloween (also Hallowe'en) is thought to have derived from a pre-Christian festival known as Samhain (pronounced "Sah-wen") celebrated among the Celtic peoples. The various peoples whom we now refer to as "Celts" once lived across Europe, but in time came to inhabit the areas known today as Ireland, Scotland, Wales, Brittany, and Cornwall. Modern Irish, Welsh, and Scots peoples are the descendants of these peoples, as are their Gaelic languages.

### History

Samhain was the principal feast day of the year; it was the New Year's Day of a year that began on 1 November. Traditionally, bonfires were lit as part of the celebration. It was believed that the spirits of those who had died during the previous twelve months were granted access into the otherworld during Samhain. Thus, spirits were said to be traveling on that evening, as the Celtic day was counted from sundown to sundown.

Scholars know little about the actual practices and beliefs associated with Samhain. Most accounts were not written down until centuries after the conversion of Ireland to Christianity (c. 300 C.E.), and then by Christian monks recording ancient sagas. From the evidence, we know that Samhain was a focal point of the yearly cycle, and that traditions of leaving out offerings of food and drink to comfort the wandering spirits had joined the bonfire custom. Also, the tradition of mumming—dressing in disguise and performing from home to home in exchange for food or drink, as well as pranking, perhaps in imitation of the wandering spirits, or simply as a customary activity found throughout Europe—had become part of the occasion. With the acceptance of Christianity, the dates of the pre-Christian festivals were used as occasions for church feast and holy days. The first day of November became, in the sixth century, the Feast of All Saints, or All Hallows. Many of the folk traditions surrounding this occasion continued, and the Eve of All Hallows, Hallow Evening, has become conflated into the word "Hallowe'en." In the ninth century, 2 November was assigned the Feast of All Souls, a day set aside for prayers for all the faithful departed who had died during the previous year.

Halloween was brought to North America with Irish and British colonists, although it was not widely observed

until the large influx of European immigrants in the nineteenth century, especially the Irish fleeing the potato famine in the 1840s and thereafter. In the United States, Hallowe'en, celebrated on 31 October, was a time for parties and pranking. As a festival of autumn, the fruits, vegetables, and foods associated with it are those of the harvest. Games were and are still played with apples, and the primary symbol of Halloween is the jack-o'-lantern, the great, carved pumpkin. Likewise, both apple pie and pumpkin pie are commonly served.

### Samhain in Ireland

In Ireland, however, Halloween is much more a harvest festival than it is in the United States, where Thanksgiving has become the official day of thanks for abundance. As Samhain, November Eve was one of the four great quarter days of the year, each one marking the beginning of a new season. Samhain also marked the start of a new year. Halloween commands a place of honor in Ireland today greater than in the United States. And in fact it functions much like Thanksgiving does here. Family meals and a gathering of relatives are common. There is pranking throughout the season, and Halloween rhyming, in which young people go from door to door for weeks in advance of 31 October, present a rhyme or perform a song of some sort, in return for nuts, apples, or money. The money is spent on fireworks. Also well in advance of the actual day, lanterns are carved out of large turnips, called swedes, or rutabegas in the United States. These are given a face and a handle, and are carried about or set on walls to create a spooky atmosphere. When the old tradition of the turnip lantern was brought to the new world, settlers found the already hollow pumpkin to be preferable to the hard turnip, and so the pumpkin replaced the turnip in the United States. But the pumpkin is a fruit introduced to Europeans by Native Americans and is not native to Ireland, Great Britain, or the rest of Europe.

By carving a face on a turnip or a pumpkin, one transforms the organic item into a cultural one. The jack-o'-lantern is the wandering spirit of a man who was refused entry into either heaven or hell in the afterlife. He is condemned to wander this earth, carrying a lantern to guide his way. He is a trickster; he will lead hapless souls who follow his light to no good. The turnip lantern is said to represent the spirits of the dead—ghosts. The organic

Apple dunking was a popular Halloween activity in nineteenth-century America, as shown here in an 1879 engraving. ROUGHWOOD COLLECTION.

items are made to reference the supernatural. Also, they are turned into another kind of cultural item: food. Pumpkin pies and mashed turnips are foods of the season, and represent domestic aspects of Halloween. The wild, unpredictable outside and the safe, nurturing inside are two poles of this festival. Halloween combines danger and safety, as when trick-or-treaters in the United States are invited in for cider and doughnuts. In Ireland, the inversive elements usually precede the day itself, which is given over to parties, special meals, and traditional games. These games are often played with the seasonal foods, such as dunking for apples, but they are also used in a playful way as divination games. For instance, Halloween in Ireland is also known as Nut Crack Night, because a common game is to place two nuts together near the hearth, name them for an adolescent or courting couple, then see what the effect of the heat is on the nuts. If they explode and pop away from each other, their relationship is doomed.

Divination and Halloween food come together in the apple tarts (pies) and the cakes known as barm brack. Barm brack means speckled bread. It is a corn loaf, and it is baked with tokens inside, usually a ring, but also a thimble, or a button. To get the ring means you will be married; the button suggests bachelorhood for a man, and

a thimble, spinsterhood for a woman. There may be other tokens as well. The apple tart is also baked with charms, usually a coin (preferably silver). This means good luck for the recipient. These food customs are widespread in Ireland—one sees the bakeshops advertising their apple tarts and barm bracks “with rings and mottoes.” Likewise, in the supermarkets, quantities of apples, hazelnuts, peanuts in the shell (called monkeynuts), and even coconuts are displayed alongside soft drinks and false faces.

Many are the divination games and rites of Halloween. It is said, for instance, that one should peel an apple continuously, so that the peel is in one long piece, and then toss it over one’s left shoulder. The peel will land and form the initial of one’s future love. Typically, these games are played by girls, to whom the indoor, domestic, nurturing realm is given, while the adolescent boys collect bonfire materials and engage in games of macho daring with firecrackers. Halloween is in these ways very gendered.

According to some accounts, the Halloween supper has featured a roast fowl or even meat, but as the day before a Holy Day of Obligation in the Catholic Church, Halloween has traditionally been a day of abstinence from meat. The dishes most associated with Halloween in Ireland—colcannon, champ, and boxty—are all made from root vegetables and earthy harvests such as potatoes and cabbage. Champ is mashed potatoes, frequently with leeks, and served with a pool of melted butter in the top. Colcannon is potatoes and cabbage. Boxty is mashed potatoes mixed with grated raw potatoes, onion, and cabbage, which are then boiled, cut into portions and fried.

These traditional foods are emblematic of Halloween for many in Ireland. Sometimes, portions were left out for the fairies. In an article published in 1958, K. M. Harris quotes a man who recalls his mother putting salt on the head of each child to prevent them from being taken away by the “wee people” on Halloween. He also recounts her placing a thimble-full of salt on each plate. If the salt fell down that person would die in the next twelve months. These beliefs indicate the continued association of food with the supernatural, and perhaps echo the “old” new year’s day of Samhain in the idea that what happens on this night affects the next twelve months.

Periods of transition and seasonal change frequently are felt to be times when the barriers between the natural and the supernatural—between our world and the otherworld—are opened. During such times, spirits and otherworldly creatures such as fairies are especially active. They are dangerous and must be appeased; thus the offerings of food. But they are also tricksters, and can be imitated, thus lending an air of inversion to Halloween.

### Halloween in the United States

In the United States, 31 October has become a major celebration that appeals to adults as well as children, as shown by the elaborate homemade and store-bought dec-

orations people use to decorate their homes, and also by the adult street festivals, masquerades, and parties found all over the United States. Commercially, Halloween has become second only to Christmas in the amount of revenue it generates.

Ironically, by the mid-twentieth century, Halloween in the United States had become almost exclusively a children's event. The custom of trick-or-treating (the American version of Halloween rhyming) seems to have been introduced in the 1930s as an alternative to the children's pranking activities—sometimes dangerous, such as logs in the road; always a nuisance (Tuleja, 1994). Trick-or-treating became a widespread activity after World War II. While treats could include apples and homemade sweets, the favored treat was commercially produced candy. In the United States, then, Halloween has always reflected the commercial culture of capitalism. Apocryphal stories known as “urban legends” have circulated about poisoned treats and apples with razor blades hidden in them. While there has been no substantial verification of the stories, the belief is widespread. The result is that homemade treats and natural fruits are looked at suspiciously—many communities offer Halloween treat X-raying services. Now so more than ever, the commercially produced sweet is preferred (Ellis, 1994).

By the late twentieth century, as the generation that had enjoyed Halloween as children became adults, the holiday returned to being one in which different age groups engaged. College students hosted large costume parties. Cities such as New York, Boston, Washington, D.C., and San Francisco had major street festivals. As a day of public costuming and inversion, a time when people confronted images of the taboo—representations of death, evil, and chaos, Halloween had long been used by the gay population as a “safe” time to parade in drag, to publicly display an identity that they must keep hidden the rest of the year. By the end of the twentieth century, the rest of the population joined them to create a kind of national Mardi Gras. Unlike the actual Fat Tuesday, however, this carnival is in the autumn, and it combines seasonal images of the harvest with images of human death (ghosts and skeletons) as well as other unspeakables. Halloween is a time when it is safe to play with our fears, to allow our demons to come out from under the bed and take center stage once a year.

**HAMBURGER.** Humans have consumed beef in scraped, chopped, hashed, and minced forms since the domestication of the cow. Its main advantage was that it was an efficient way of using many smaller parts of the cow, including fat, organs, brains, and so on. To this

## FIRST LOCATED HAMBURG(ER) RECIPE?

### To make Hamburg Sausages

Take a pound of Beef, mince it very small, with half a Pound of the best Suet; then mix three Quarters of a Pound of Suet cut in large Pieces; then season it with Pepper, Cloves, Nutmeg, a great Quantity of Garlic cut small, some white Wine Vinegar, some Bay Salt, a Glass of red Wine, and one of Rum; mix all these very well together, then take the largest Gut you can find, stuff it very tight; then hang it up a Chimney, and smoke it with Saw-dust for a Week or ten Days; hang them in the Air, till they are dry, and they will keep a Year. They are very good boiled in Peas Porridge, and roasted with toasted Bread under it, or in an Amlet.

SOURCE: Hannah Glasse. *Art of Cookery Made Plain and Easy*. 6th ed. London, 1758, p. 370.

mixture could be added parts of other animals, plants, spices, flavorings, and adulterations. The resulting product can be easily shaped into different forms and prepared in a variety of ways—raw in steak tartare, molded into flat cakes or croquets, baked in a loaf, boiled and served in soups, barbecued or roasted and served on a bun, fried into meat balls, or stuffed into sausages with spices and herbs for later consumption.

### Origin of Hamburger

The invention of the twentieth-century hamburger sandwich is the result of long developmental processes. Beginning in the fifteenth century, minced beef was a valued delicacy throughout Europe. In northern Germany, lightly fried chopped meat was called *Frikadelle*. Similar words are found in other European languages, and the root may be “farce,” deriving from Latin *farcere* (to stuff). In English the term “forcemeat” was defined by Randle Holme in “The Academy of Armory” (Chester, 1688) as “meat with a stuffing of herbs, or other things made to that purpose.”

Hashed beef was made into sausage in several different regions of Europe. In places such as Bologna, Russia, and Hamburg, beef was often combined with other meats and other ingredients. The German city of Hamburg was known for its beef sausage, which migrated to England by the mid-eighteenth century. One recipe, titled “Hamburg Sausage,” appeared in Hannah Glasse’s 1758 *The Art of Cookery Made Plain and Easy*. It consisted of chopped beef, suet, and spices. Although the author recommended that this sausage be served with toasted

bread, no evidence suggests that the sausage was served as a sandwich.

Hannah Glasse’s cookbook was also among the most common in Colonial America, although it was not published in the United States until 1805. This American edition did contain the “Hamburg Sausage” recipe with slight revisions.

The frequently cited “Hamburg Steak” on the Delmonico’s restaurant menu dated 1834 was neither served as a sandwich nor composed of ground beef. With the popularization of the meat grinder in America about 1850, ground beef became a possibility. Recipes for it appeared in cookbooks from other countries, such as in Henriette Davidis’s *Praktisches Kochbuch für die Deutschen in Amerika*. In American cookbooks, these recipes were frequently called “Beefsteak à la Hamburg.” This recipe was so associated with the United States that the 1899 edition of Blüher’s *Rechtschreibung der Speisen und Getränke* reported without explanation that chopped beefsteak was called “Hamburg steak” in America. Ground beef was also called “Salisbury steak,” which was named in honor of the American physician James H. Salisbury (1823–1905), who wrote *The Relation of Alimentation and Disease* (New York, 1888). Salisbury believed that scraped lean beef, flattened into cakes and broiled, was among the best foods for those who were ailing. As scraping beef was a difficult task, common recipes for it just recommended grinding the beef, a process not recommended by Salisbury. Scraped or ground, Salisbury steak could be served with toast, but it was not served as a sandwich.

### The Sandwich

The sandwich—a filling between two slices of bread that can be consumed by hand—is said to have been popularized by the Fourth Earl of Sandwich (1718–1792). This mode of eating became so popular in England that it was mentioned in several diaries and in Samuel Johnson’s 1755 *Dictionary of the English Language*. Shortly thereafter, cooks and hosts began experimenting with various fillings other than sliced beef.

Sandwiches migrated to the United States before the Civil War. In the mid-nineteenth century, sandwiches consisted of a filling composed of lean slices of cold meat between two thin pieces of bread flavored with mustard and ketchup. They were served in bars and saloons, where patrons could easily consume them without the need of knives, forks, or plates. During the late nineteenth century, interest in the sandwich rapidly expanded to include boned fish, sardines, cheese, boiled eggs, stewed fruit, chopped nuts, mushrooms, chicken, watercress, sardines, and jelly and jam. Many salads, such as chicken and lobster, were converted into sandwiches. By 1900, hundreds of different fillings were consumed in sandwiches.

### Hamburger Sandwiches

Several legends have grown up concerning who first served hamburger sandwiches in America. A hamburger

sandwich is defined as a hot ground-beef patty between two slices of bread. It is not likely that any of the early claims put forth are accurate: sandwiches were composed of thin bread requiring thin fillings. Thin bread would also not have been able to contain the juices exuded from hot ground hamburger.

The first known published reference to a “hamburger sandwich” appeared in an article in the *New York Tribune*, which noted that this “new innovation” was served at the 1904 St. Louis Exposition. While it is possible that hamburger sandwiches were constructed well before this date at small stands and diners, the fair gave them national exposure and national diffusion resulted.

Hamburgers served in stands and diners in many regions of the United States attracted the working class. In a diner in Wichita, Kansas, a short-order cook named J. Walter Anderson flattened the meat balls and placed them in a bun; he developed the first commercial bun for hamburgers. In 1916 Anderson opened his own hamburger stand and sold them at five cents apiece to attract customers. To sell sandwiches at this price, Anderson streamlined his operation. To make certain that his clients were aware of what was contained in his hamburger, he ground his own beef and let his customers watch him doing it. His business was so successful that he opened three additional stands within four years. His success brought competitors, and the streets of Wichita had many hamburger stands. In 1921 he went into business with Edgar Waldo “Billy” Ingram. Ingram repackaged Anderson’s hamburger stands architecturally into castles, and gave the operation the name “White Castle.” Ingram insisted on standardization of all the stands, and he required employees to maintain strict standards of cleanliness, eventually requiring uniforms. This was extremely successful, and White Castle began expanding beyond Wichita. By 1924 the company had expanded to Omaha, then to Kansas City, then St. Louis, and the expansion continued. Ingram declared White Castle to be a national operation with forty-four outlets by 1930. He standardized the operation by opening meat-processing and bun-baking operations.

White Castle imitators, including some with the word “white” in their name, such as White Tower, spread across the United States. Ed Gold launched another hamburger chain, Wimpy Grills, in 1934. This featured the ten-cent “Wimpy” burger named after the cartoon character J. Wellington Wimpy, who immortalized the phrase: “I would gladly pay you tomorrow for a hamburger today” in a Popeye cartoon released in 1929. Wimpy Grills was the first fast-food corporation to expand abroad. Another competitor was Bob Wien, who founded Bob’s Big Boy chain in southern California in 1936. He featured an upscale double-patty burger and franchised his operation, which quickly spread from coast to coast.

Within a few decades of the launch of White Castle, the hamburger had become America’s national sand-

wich. Through small hamburger stands and national franchise chains, hamburgers were sold through hundreds of outlets throughout America.

### McDonald's

The prewar enlargement paled by comparison with the expansion of hamburger establishments after World War II. Returning from the war, many military personnel married, had children, bought cars, and moved to the suburbs. Focusing on those suburbanites with growing families and stretched incomes, Richard and Maurice McDonald designed a hamburger restaurant incorporating assembly-line efficiency into a commercial kitchen. This efficiency helped them to reduce their expenses and therefore permitted them to sell hamburgers at a low price. They hoped that the lower price would increase the number of customers, generating a greater volume with higher profits. To test their ideas, they opened an octagonal-shaped hamburger stand in San Bernardino, California, in 1948. Their operation did not include indoor tables, and it required that customers line up to place their orders and then eat in their cars: this eliminated the need for waitresses, which further reduced their expenses. The McDonalds sped up the process of making hamburgers through a series of innovations. They also decided to concentrate on selling just a few items: hamburgers, cheeseburgers, French fries, sodas, and shakes. These efforts to streamline and mass-produce hamburgers paid off. In 1951, they grossed \$275,000.

As efficient as their internal operation was, the McDonald brothers concluded that they needed a new architectural design for the outside of their restaurant. Richard came up with the idea of constructing “golden arches” right through the roof which sloped upward toward the front, thus creating one of the most well-known architectural symbols in the world.

With the success of their newly designed operation, the McDonald brothers made another important decision: they franchised their operation. Franchising permitted others to build McDonald's drive-ins throughout the nation that were based on the design developed in San Bernardino. Those receiving franchises paid the McDonald brothers a fee and a percentage of their sales. In 1953 newly-designed McDonald's franchises opened in Phoenix, Arizona, and Downey, California.

At this time, McDonald's was just one of several new fast-food hamburger chains. In Los Angeles, Carl Karcher started selling hamburgers in 1946. In San Diego, Jack in the Box had been launched in 1951 and sported the first drive-through service. Three years later in Miami, James McLamore and David Edgerton founded Insta-Burger King, which later evolved into the Burger King chain.

To make the shakes quickly, the McDonald brothers purchased Multimixers—machines that mixed six shakes simultaneously. Ray Kroc, a Multimixer salesman, visited the McDonald brothers' operation in 1954 and was so impressed with their efficient operation that he arranged with the McDonald brothers to sell franchises. In 1955, Kroc opened his own McDonald's restaurant in Des Plaines, Illinois, and streamlined the operation even further. By the end of 1957, there were thirty-seven McDonald's. Two years later, the total exceeded one hundred establishments, and this doubled the following year. In 1961 Kroc bought out the McDonald brothers for \$2.7 million and opened Hamburger University in Elk Grove, Illinois. McDonald's operations throughout America rapidly expanded.

McDonald's success encouraged competition, and many other fast-food chains adopted methods developed by the McDonald brothers and Kroc. Dave Thomas opened his first Wendy's restaurant in 1962 in Columbus, Ohio. Fast-food establishments underwent tremendous growth beginning in the mid-1960s. By 2000 there were more than 11,800 McDonald's, 6,298 Burger Kings, and 3,721 Wendy's fast-food establishments in the United States. Since there are an estimated 160,000 fast-food restaurants, it is estimated that the first job of one out of ten Americans is in a fast-food establishment.

### Problems

Despite the rapid success of fast-food and soft-drink enterprises throughout the world, hamburgers and fast food have been condemned almost from the beginning. Until the arrival of White Castle, many potential customers avoided hamburger stands because of the lack of cleanliness of some establishments. Also, as low cost was an important factor in the hamburger business, many sellers adulterated the ground beef with other ingredients, leading many Americans to consider the hamburger an unhealthy food. In *100,000,000 Guinea Pigs* (1933), Arthur Kallet and F. J. Schlink claimed that hamburgers contained preservatives, which restored the color of the ground beef and destroyed the odor of spoilage.

Another concern has focused on fast-food advertising targeted at youth. McDonald's, for instance, developed cartoon characters such as Ronald McDonald. The "Happy Meal" with toys was launched in 1979. McDonald's has subsequently added children's play areas to many establishments and, like Burger King, has developed numerous tie-ins with major children's motion pictures.

Fast-food chains have been sensitive to a variety of health and environmental issues. For instance, McDonald's has reduced the fat content of its hamburgers, encourages recycling in some restaurants, refuses to buy beef from Brazil, and changed the wrappings of Big Macs and Quarter Pounders to make them more biodegradable.

Eric Schlosser's *Fast Food Nation: The Dark Side of the All-American Meal* maintains that the enormous growth of the fast-food industry has caused conditions in the big slaughterhouses to pose serious health concerns. Schlosser and others also blame fast food for a rise in obesity, which is among America's most serious health problems.

There has been heated criticism of the effects of fast food on local cultures and businesses. Serious nutritional, environmental, and cultural questions about fast food remain. As the homogenization of food choices continues worldwide, some consider the rapid expansion of fast-food chains as examples of an insidious American imperialism that is destroying local cultures and values. McDonald's success abroad has caused deep resentment by others who see the company as a symbol for the United States, and who believe that McDonald's expansion threatens local culinary traditions. In France, a sheep farmer named José Bové demolished a McDonald's restaurant that was nearing completion. Similar actions have occurred in other European countries.

### Globalization

Despite condemnation throughout the world, the hamburger sandwich is one of the most successful foods in the world. The attraction of the hamburger is that it is inexpensive, convenient, and filling. Hamburgers are also versatile. At the minimum, hamburger sandwiches consist of just cooked ground beef in a bun. To this can be added hundreds of sliced and diced vegetables, condiments and spices, the most common of which are tomatoes, onions, mayonnaise, ketchup, mustard, pickle relish, salt, and pepper. Hamburger sandwiches with special seasonings and ingredients have proliferated. In 1984, Gyula Décsy's *Hamburger for America and the World* catalogued more than eight hundred hamburgers in the United States alone. These were a small fraction of the variety of hamburgers available today.

Hamburger establishments also caught on quickly in Canada and the United Kingdom. McDonald's opened its first Canadian restaurant in 1967 and created its International Division in 1969. By 1988 McDonald's had

2,600 locations abroad. Six years later, that number exceeded 4,500 restaurants in 73 other countries. In 2002 there were more than 28,000 restaurants in about 120 countries. McDonald's has over 1,000 restaurants in Japan alone. Measured by volume of customers, the most popular restaurant in Japan is McDonald's. France has 538 McDonald's restaurants; Australia, 615; Germany (the home of the original "hamburger"), 743; United Kingdom, 693; and Canada almost 900. The world's largest McDonald's is located near Red Square in Moscow, where a Big Mac lunch costs the equivalent of a week's paycheck. When McDonald's opened its first restaurant in Minsk, over 4,000 Belorussians showed up, forcing the operators to call in the police for crowd control. McDonald's boasts 127 restaurants in China—one of which overlooks Tiananmen Square in Beijing. Today, McDonald's international sales are \$15 billion out of a total of almost \$32 billion. Of its total revenue, 59 percent of its corporate profits are generated by restaurants in countries other than the United States.

There are many reasons for the success of fast-food chains in other countries. Most chains have adapted to foreign cultures, including revising the ingredients in hamburgers. In addition to efficient service and cultural sensitivity, other factors contributing to this success abroad are cleanliness of fast food establishments, family atmospheres, clean bathrooms, and air-conditioning. At the beginning of the twenty-first century, there were few countries that did not sport a fast-food establishment selling hamburgers. Foreign hamburger establishments are expanding at a faster pace than are hamburger establishments in the United States. With this rapid expansion, hamburgers are now a global food.

**HARVESTING.** Harvesting is the act of removing a crop from where it was growing and moving it to a more secure location for processing, consumption, or storage. Some root crops and tree fruit can be left in the field or orchard and harvested as needed, but most crops reach a period of maximum quality—that is, they ripen or mature—and will deteriorate if left exposed to the elements. While the major factor determining the time of harvest is the maturity of the crop, other factors such as weather, availability of harvest equipment, pickers, packing and storage facilities, and transport are important considerations.

Economic and marketing issues are often even more important than considerations of maturity in deciding when to harvest a commodity. Before the crop can be harvested, the grower must be sure that there is a demand for the crop and that the price is sufficient to make harvesting the crop profitable. If the price is less than adequate to cover the costs of production, harvesting, and marketing, growers are faced with the difficult decision whether to harvest and store the crop, to wait for a better market, or to cut their losses and leave the crop in the field.

#### The Process of Harvesting

Harvesting can be separated into three steps. The plant part of interest must be identified, detached from the rest of the plant, and then collected in a container suitable for transport from the field. The harvesting of all the major agronomic crops (grains of cereals and legumes) has been mechanized. The resistance of dried cereal and legume seeds (for example, corn, rice, wheat, and soybeans) to physical damage allows the first and second steps to be combined in a threshing machine or combine that separates the seeds from the rest of the harvested plant. The grain (seeds) is then loaded in bulk containers and transported to silos for additional cleaning, grading, fumigation, and temporary storage.

Community Supported Agriculture (CSA) started in Japan in 1965 and has since spread to many parts of the world. Families buy shares of a season's crop and are delivered food on a weekly basis. Some farms allow shareholders to harvest the food themselves. This family is gathering broccoli. © DAVID MARTINEZ/CORBIS.

In contrast to the dry grains and legumes, most horticultural crops (fleshy fruits such as apples and tomatoes, ornamentals, and vegetables) are hand harvested for the fresh market. Some mechanical harvesting is done, but the damage incurred is usually so severe that the fruits and vegetables are only fit for processing. Some fruits (for example, apple, pear, and tomato) evolved to ensure seed distribution by enticing animals to eat the attractive (in appearance, aroma, and flavor) fruit. Therefore, they are almost always attached to the plant by a specialized structure that contains an "abscission zone" which permits the ripe fruit to be easily separated from the tree. Other fruit, such as bananas, citrus, peppers, and all vegetables (for example, cabbage, broccoli, carrots, lettuce, and squash) do not develop an abscission zone and must be cut from the plant.

Only human beings have the unique combination of eyes, brain, and hands that permits the rapid identification and harvest of delicate and perishable materials with minimal loss and bruising. Some mechanical aids such as cherry pickers, ladders, picking bags or baskets, stem clip-

pers, and wheelbarrows are used by harvesters to make their work easier, faster, and safer. Harvesters can be trained to select only those fruits or vegetables that are of the correct maturity, size, or shape, thus greatly reducing the amount of material that must be removed on the sorting and grading line in the packing shed. In fact, many vegetables and berries are harvested directly into retail containers without further sizing or grading. Most other horticultural crops are harvested into field bins that are taken to packing sheds where the commodities are cleaned, sorted, graded, inspected, packed, cooled, and stored before being transported to regional markets.

### The Social Importance of the Harvest

The time of harvest is one of the most important phases of the agricultural calendar since it marks a point in time when the crops have survived natural disasters and are ready to be gathered in. The period in late summer just before the harvest could be a time of famine because of poor harvests the preceding season or an inability to store food from the last harvest. It is not surprising then that the fall harvest festivals were such joyous times, for they heralded the end of this all too frequent seasonal famine and ushered in a time of plenty. There have been harvest celebrations for as long as people have gathered seasonally abundant food for storage and later consumption. Cultures as diverse as the Chinese, Egyptian, Greek, Hindu, Mayan, and Roman developed elaborate harvest customs that included songs, rituals, prayers, and special dishes.

Thanksgiving Day is perhaps the most universally observed harvest ritual in the United States and Canada, although these days are not communal in the sense of traditional village feasting. In the United States, Thanksgiving Day celebrates the first harvest of Dutch and English settlers who arrived in America almost four hundred years ago aboard the *Mayflower*. About fifty years before these Pilgrims, the observation of another Thanksgiving Day was started in what is now Newfoundland. Centuries later they were recognized as official holidays in their respective countries. However, for thousands of years before the European invasion, Native Americans had developed many traditional harvest celebrations. The Wampanoag Indians who inhabited the site occupied by the Pilgrims had three thanksgiving harvest festivals during the year: one for the maple tree and its syrup, one for picking berries, and one for the food they had grown and gathered that year.

County and regional fairs were often scheduled after the harvest so local farmers could sell some of their harvest to merchants, exchange experiences about the previous season, learn new farming techniques, exhibit their finest crops, compete for awards, and generally engage in a communal celebration. Other harvest-related events included parades, special religious services, and a large feast with traditional native dishes. In North America these include cranberry sauce, pumpkin pie, succo-

tash, sweet corn, pecan pie, turkey, and wild rice stuffing. Succotash is a native North American dish that can be prepared today by combining whole-kernel sweet corn with Lima or broad beans in a sauce made from cream and flour. The cream (1 cup) and flour ( $\frac{1}{4}$  cup) are boiled for a few minutes with constant stirring, and then the sweet corn (one cup) and beans (2 cups) are added and the mixture heated for another 8 minutes. Addition of meat stock, bits of meat, green peppers, squash, and seasoning transforms this basic recipe into the many regional variations consumed throughout Eastern North America.

The Harvest Home celebrations of earlier times are dying out as the number of people engaged in farming declines because of mechanization, and as urban populations become disconnected from the actual growing of crops. In the past, the whole rural community worked together to harvest crops before the storms of late autumn arrived. The first or last fruits of the harvest were often accorded special religious significance and either offered to the gods, or kept safe as a talisman to be used to protect the planting of the crop next season. Cutting of the last sheaf and carrying it in procession to shelter symbolized the bringing of the harvest home, and was greeted with great rejoicing accompanied by music, dancing, and elaborate feasting. One of the traditional Harvest Home dishes was frumenty, a wheat pudding made with boiled milk, almond extract, honey, egg yolk, and raisins. The milk ( $1\frac{3}{4}$  cup), almond extract ( $\frac{1}{2}$  teaspoon), and honey (2 tablespoon) are brought to a boil, the heat reduced, and the cracked wheat (1 cup) added with stirring until all the liquid is absorbed (about 15 min.). The yolk of one egg is then stirred in and  $\frac{1}{4}$  cup of raisins is added. The pudding is served either hot or cold.

**HEALTH AND DISEASE.** The relationships among food, health, and disease are myriad and complex. We consume food every day, and it provides the resources we need to carry out life-sustaining functions. Hence it comes as no surprise that one's diet can affect profoundly

one's daily and long-term physiological health and well-being. Qualities of a diet and the foods that comprise it have the potential to make one sick, but they also can act to reduce one's risk of acute or chronic diseases.

All of the formal medical traditions of the world recognize a close connection between diet and an individual's health. One theme common to Mediterranean, Middle Eastern, and South and East Asian traditional medical systems is the ascription of humoral qualities to foods (for example, foods that are "heating" or "cooling" to the body). In these traditional systems, an individual's diet is manipulated to include or exclude foods with specific properties in order to correct putative humoral imbalances or disease states. In contemporary biomedicine, the link between food and disease most often is articulated with regard to the compositional qualities of foods and the ways that diets high or low in specific foods (and hence nutrients and other plant constituents) have harmful or beneficial effects on the body.

#### Benefits of Nutrient Diversity

There are numerous ways in which diets comprised of specific foods containing or lacking a given nutrient contribute to health or disease. For example, a diet that includes few or no animal products may result in anemia due to a deficiency in iron and/or vitamin B<sub>12</sub>. On the other hand, a diet high in animal products but low in fruits and vegetables may contribute to specific vitamin deficiencies. Scurvy (a disease caused by vitamin C deficiency) was recognized first among sailors on long-distance sea voyages, as they had no source of fresh fruits or vegetables. An unprocessed corn-based diet is known to result in the disease pellagra, caused by a deficiency of niacin, one of the B vitamins. Up through the early twentieth century, there was a well-defined "pellagra belt" through the southern United States, where corn was consumed widely.

A diet comprised of diverse foods generally is considered to be the best way to prevent nutrient-deficiency diseases. Early humans lived by hunting and gathering, and they ate a broad array of plant and animal foods, although this varied by season and geography. Modern hunter-gatherers of the Kalahari Desert in southern Africa are known to exploit more than eighty species of plant foods, and no specific nutrient deficiencies have been reported among these groups. However, with the transition to agriculture, which happened in many parts of the world around 10,000 years ago, dietary diversity declined notably as populations began to cultivate a narrow array of staple crops (such as wheat, rice, potatoes, and millet). Iron deficiencies and severe growth deficits due to undernutrition become apparent in the skeletons of early farmers.

#### Effects of Food Processing

Some of these nutritional problems were resolved as populations evolved different means of processing staple

foods that enhanced dietary nutrient profiles. Indeed, in the postagricultural period, food-processing techniques became crucial for reducing the negative health impacts of reliance on a few foods. Native populations of the Americas that had a long tradition of reliance on maize (corn) prepared it in such a way as to avoid the problem of niacin deficiency. Corn was boiled in a solution containing lime (calcium carbonate, ash, etc.); this process resulted in the liberation of niacin from an undigestible complex, and also improved the food's amino-acid balances. When corn was introduced to Europe during the Columbian period, the lack of a tradition for its processing led to outbreaks of pellagra. A similar example is the leavening of wheat to make bread, or fermentation to make beer. Both of these processes increase the bioavailability of the minerals calcium, iron, and zinc. When soybeans are processed into bean curd, as is common in East Asia, they lose their protease inhibitors, which interfere with protein digestion.

On the other hand, it is also the case that some food-processing techniques—such as heating, boiling, or drying—can destroy vitamins in foods. Vitamin C degrades in the presence of heat and aridity; folic acid and thiamine likewise are sensitive to heat. Some of the other B vitamins break down in the presence of alkaline or acidic conditions. Others, such as vitamins B<sub>6</sub> and B<sub>12</sub>, are quite stable under most cooking conditions. Milling and polishing rice into smooth white grains, which are valued highly in East Asian cuisine, reduce the protein and thiamine content of rice, and contribute to the risk of the disease beriberi (thiamine deficiency). Industrial processing of foods often reduces their nutrient profile, but many foods, especially those that are consumed widely such as cereals, are enriched to replace lost nutrients. In addition, grilling or broiling meats until they are well-charred has been associated with the production of the chemical compound Benzo(a)pyrene, which has been linked to gastrointestinal cancers.

### Nonnutritive Food Components

When diets are derived largely from plant foods, particular combinations of food are known to improve the overall dietary quality, particularly with respect to the balance of essential amino acids. Corn, for example, is low in the amino acids lysine and tryptophan, but in native American cuisine, corn is often combined with legumes that are rich in those amino acids. Likewise, the combination of rice and legumes can provide the full array of essential amino acids. A peanut butter sandwich, a staple in the diet of many American children, contains complementary amino acids from the wheat and peanuts.

However, it is not only the nutrient composition of foods that is relevant to disease. Other qualities of foods—especially plant foods—recently have been found to contain other chemicals that reduce the risk of certain diseases. Phytochemicals derived from plant foods may

reduce the risk of some cancers, while others may protect against heart disease and/or diabetes. Some potentially important phytochemicals include polyphenols (in red wine and green tea) and carotenoids (in orange, yellow, and green vegetables). Many of these have been found to have antioxidant effects and may prevent cell damage from oxygen-free radicals. Widespread consumption of red wine has been credited by some with the “French Paradox,” the observation that, although the French tend to eat foods high in fat, their consumption of red wine may offset some of the risk of cardiovascular disease usually associated with such diets. Phytoestrogens, a form of isoflavones found in legumes such as soybeans, may reduce the risk of many cancers, especially breast cancer, by binding to estrogen receptors, and these also may reduce bone loss associated with osteoporosis. Proteins in soybeans also may reduce cholesterol levels and thus reduce the risk of heart disease. The organosulfur constituents of garlic may inhibit platelet aggregation and reduce blood lipids, thereby reducing the risk of coronary heart disease. Tannins (found in tea, coffee, cocoa, red wine, and some legumes and grains) and phytates are hypoglycemic, and may contribute to reduced risk of diabetes.

Other plant compounds have links to infectious disease, such as the protozoan disease malaria, which is a common disease (and often life-threatening) in tropical and semitropical areas. Manioc (*Manihot esculenta*; also called cassava or yuca), a widely cultivated root crop in the tropics, contains cyanogens, which appear to inhibit the growth of the malaria parasite in red blood cells. Likewise, fava beans contain vicine, a potent oxidant that disrupts malarial reproduction in red blood cells. However, individuals who are deficient in the enzyme G-6PD (a deficiency most common in Mediterranean populations) are susceptible to the potentially fatal anemia, favism, because their red blood cells are extremely vulnerable to destruction by potent oxidants such as vicine.

Many secondary compounds in plants do not have such salutary effects, or their benefits are tempered by potential negative effects on health. The cyanogens in manioc, lima beans, and other foods can interfere with thyroid function, glucose metabolism, growth and development, and other important physiological functions. Cruciferous vegetables such as cabbage contain thiocyanate compounds that act as goitrogens, and thereby contribute to thyroid disease. Tannins, which are distributed widely among plant foods, inhibit protein digestion and interfere with iron absorption. The ingestion of solanine, a glycoalkaloid found in commercial strains of potatoes that have been exposed to light, or in many wild varieties, can lead to serious gastrointestinal and neurological symptoms. Interestingly, traditional modes of consuming potatoes among Andean populations appear to reduce the risk of solanine exposure; their potatoes are consumed often with a clay-based slurry, which effectively detoxifies them.

## Food-Consumption Concerns Linked to Population Profiles

There are cases in which the health effects associated with the consumption of particular foods vary in significant ways among diverse populations. For example, the ability to produce the enzyme lactase (which breaks down the milk sugar lactose) in adulthood is rare among human populations. This ability persists in highest frequencies through adulthood among northern Europeans and pastoral populations in Africa and other areas. Fresh milk consumption played an important role in maintaining health in the history of these populations, and they evolved lactase persistence as a dietary adaptation. When adults with low levels of small-intestinal lactase activity consume fresh milk (the food highest in lactose), they often experience cramps, bloating, diarrhea, and other forms of gastrointestinal distress. This is less of a problem when milk is consumed after processing into yogurt or cheese, as lactose is either fermented or removed during their production.

In populations that only recently have begun relying on wheat production there is a high frequency of celiac disease, an allergic response to wheat protein (gluten). There is some suggestion that African Americans may be more sensitive to salt than are other sectors of the population, and that, consequently, salt consumption by African Americans increases blood pressure and contributes to an incidence of hypertension greater than in other groups.

In the most general sense, both underconsumption and overconsumption of foods can lead to chronic disease. Not surprisingly, these two ends of the consumption spectrum tend to occur in poor and wealthy populations, respectively. It is estimated that more than 1.2 billion people suffer from deficiencies of calories and protein. A similar number suffer from problems related to the overconsumption of calories. Both are associated with deficiencies of micronutrients. It has been suggested that more than half of the world's disease burden derives from nutrition-related sources.

Overconsumption of calorie-rich foods became the norm in wealthy countries during the late twentieth century. Such foods became mass produced, more readily available, and relatively inexpensive. Today supermarket shelves are lined with potato chips, candy, cookies, crackers, soda, and all kinds of other calorie-dense foods. Fast-food restaurants specialize in ever-larger servings of high-calorie foods that are quickly prepared and consumed. Most of these are highly processed, and although they are rich in calories, they are often low in vitamins, minerals, and phytochemicals. It is widely accepted that, when combined with a sedentary lifestyle, diets high in such foods contribute to a broad array of chronic health conditions, most significantly cardiovascular disease (CVD), diabetes, cancer, and hypertension. It is now estimated that more than half of Americans are overweight, and almost one-quarter are obese, which is itself a risk

factor for these diseases. In addition, an increasing number of children are now obese, and "adult-onset" (Type 2) diabetes is appearing with alarming frequency in adolescents. More than 75 percent of all mortality in the United States is due to CVD and cancer, but death rates from stroke and heart attacks have declined since the 1970s. This has been attributed, in part, to reduced consumption of saturated fat from red meat, whole milk, butter, and lard. There are several studies indicating that a low-fat diet based largely on vegetables, fruits, whole grains, legumes, with relatively small amounts of animal protein (especially from fish) is associated with increased longevity and reduced risk of chronic disease.

Problems related to the overconsumption of high-calorie foods are not unique to the industrialized world. As countries are integrated into the global economy and populations increasingly become urbanized, there has been a global shift in dietary patterns and health conditions that appear to accompany those new consumption habits. Interestingly, such changes are remarkably consistent across countries, and may reflect a panhuman preference for foods rich in calories, which historically have been quite limited in the diet. Generally the consumption of fats and sweets has increased, and the use of traditional whole-grain foods and traditional modes of processing has declined. Fast-food outlets such as Kentucky Fried Chicken and McDonalds have become ubiquitous in urban centers throughout the world. Active lifestyles are being replaced with sedentism, as people move away from subsistence agriculture into clerical and factory jobs. As a result, the chronic diseases that heretofore had predominated in wealthy industrialized countries are becoming globalized. For example, the global diabetes rates seen in 2000 are expected to double by 2025, with the majority of that growth occurring in developing countries.

On the other hand, undernutrition, also referred to as protein-energy malnutrition (PEM), often occurs under conditions of food scarcity and is associated with a wide range of negative health effects. More than 10 percent of the world's population suffers from chronic hunger, and undernutrition may be responsible for as many as twenty million deaths per year. It is important to realize that hunger is not the result of too little food being produced for too many people in the world; it is essentially a problem with the way that food is distributed unevenly among the world's populations. Children are especially vulnerable to PEM, as they have higher protein and energy needs per unit of body weight than do adults. When calories and protein are chronically scarce in childhood, permanent stunting and retarded development occur. In its acute form, PEM results in wasting (dramatically reduced weight relative to height) and it is potentially fatal. More routinely, PEM increases vulnerability to infectious disease, since energy, protein, and certain vitamins and minerals play crucial roles in immune function. In environmental contexts in which

infectious disease (especially diarrheal disease) is common, the combination of PEM and infection can provoke a rapid deterioration of health that can lead to death. A common stage for this progression to manifest itself is weaning, the period when children make the transition away from breast milk (which contains nutrients and disease-suppressing maternal immunoglobulins) to an adult-type diet. It is not uncommon for children to become more vulnerable to infection when they are weaned prematurely and are unable to consume sufficient nutrient-dense foods to maintain growth.

In the 1800s, baby bottles were developed and cow's milk was developed into infant formula as an alternative to breast milk. The practice of formula-feeding peaked in the United States in the years following World War II; breast-feeding is now on the rise again in most parts of the world, although it remains uncommon past the early months in most industrialized countries. Most research amply demonstrates the health benefits of breast-feeding: substitution of formula for breast milk is associated with increased risks of numerous health problems including SIDS (sudden infant death syndrome), ear infections, diabetes, breast cancer, and allergies.

Controversy erupted in the early 1970s over the promotion of formula by multinational corporations in the developing world. Formula was marketed heavily and inappropriately, and health personnel began to encourage mothers to feed their children formula rather than nurse them. Formula, which was costly, often was prepared in dilute form with contaminated water. Its use in this way increased infant morbidity and mortality and generated much attention among the media and international health organizations, ultimately resulting in a ban on formula promotion by multinational corporations.

As the links between diet and disease have become more widely known, there has been a trend toward more healthful eating habits in industrialized societies. However, this trend is not uniform within such populations. Numerous studies have shown that obesity, the eating habits that contribute to it, and the diseases associated with it, especially diabetes, have increased among lower socioeconomic groups. The reasons behind this trend are complex, but as noted above, foods high in starches, fats, and sugars are now cheap and readily available. Those high in protein (meat, dairy products) and fresh fruits and vegetables are relatively less accessible and more expensive, and are consumed less commonly by the poor. Moreover, in the United States, fast-food outlets are locating preferentially in areas serving poorer communities. This has led to the curious, yet commonplace, phenomenon in wealthy countries whereby weight is correlated inversely with wealth. Historically, of course, the reverse would have been the case, as is still evident in many developing countries.

**HEALTH FOODS.** The concept of "health food" is attributed to the 1830s Popular Health movement whose founders included Sylvester Graham, father of graham crackers. Reacting against professional medicine, the movement emphasized temperate living, lay knowledge and health care, and health foods as part of the broader

feminist and class struggle. A simple vegetarian diet, including whole wheat, and exercise were promoted for physiological and spiritual reform to a more natural, uncomplicated life. Meat, white flour, and alcohol were among the stimulating sinful foods.

John H. Kellogg and his brother Will were the first to become millionaires from “food faddism” (Herbert and Barrett, 1981, p. 87). The Seventh-Day Adventists founded a religious colony and sanitarium at Battle Creek, Michigan, where Kellogg’s clients “detoxified” via enemas and high-fiber diets, including cornflakes. By 1899, the Kellogg cereal company’s cornflakes competed with Post Grape-Nuts, the latter a supposed cure for appendicitis, malaria, consumption, and loose teeth. Charles W. Post was a former Kellogg patient. Kellogg and the Post Division of General Foods remain giant cereal manufacturers.

While scientists quantified protein, carbohydrate, fat, and later the vitamin and mineral composition of food in the late 1800s and early 1900s, agriculture and industry augmented production. Public health sanitation and vaccinations minimized infections, and the increased stable food supply fed a growing population more fit to work the factories, farms, and military. As home economists taught the nutritional food groups recommended by the U.S. Department of Agriculture (USDA), profiteers promoted grander elixirs via speeches, newspapers, books, magazines, and doctors, dentists, and chiropractors with dubious degrees.

Beginning in 1906, the Food and Drug Administration (FDA) restricted health claims on food and drug packaging, but marketers could nevertheless exercise free speech by offering information in books, magazines, and brochures. *Prevention* and *Let’s Live* magazines began publication in 1950 and 1933, respectively; the latter was initially called *California Health News*. They promoted vitamins, food preparation, and exercise and warned of pollution dangers. In the era of World War II victory gardens, Rodale Press began publication of *Organic Gardening and Farming* in 1942; this later became *Organic Gardening* and then simply *OG*. In 1980, Rodale Press grossed \$80 million with 2.4 million *Prevention* and one million *Organic Gardening and Farming* subscribers (Herbert and Barrett, 1981, p. 99). Amway, Shaklee, and Neo-Life used door-to-door sales to distribute high-priced vitamins with brochures and books; in 1980 these three companies grossed about \$700 million from food supplements (Herbert and Barrett, 1981, p. 22).

### Health Food and the Counterculture

The 1960s and 1970s counterculture youth questioned the political and economic values of capitalism and experimented with alternative lifestyles. University students created community gardens, cooperative grocery stores, health-food restaurants, buying clubs, and organic farms. Ecology and health food became “cool.” Notions of balance were sought from formerly less acknowledged eco-

logical studies and from Eastern or Native American philosophies. In the early 1900s, USDA staff had explored sustainable Far Eastern agricultural practices, but these foods and methods received little attention until organic farming became popular in the 1960s and 1970s. Brown rice, wheat germ, honey, nuts, sprouts, and Eastern foods like yogurt, hummus, falafel, tofu, and stir-fried vegetables were considered healthy, and environmentally sound if they were produced locally and organically. Vegetarian diets, of the non-red meat, lacto-ovo, macrobiotic, and vegan varieties, were adopted to eat low on the food chain or to avoid killing animals. Sugar, white bread, and red meat were considered unhealthy.

The health-food business recognized a market in the counterculture. Adelle Davis, with books like *Let’s Eat Right to Keep Fit*, promoted vitamins and natural foods to prevent psychological metabolic disorders as well as cancer. The Atkins Diet promised thinness through consumption of protein foods, fruits, and vegetables, but few carbohydrates. While exploring non-Western religions and cultures, youth tried ethnic foods, spices, herbs, and recreational drugs. While ethnic variety entered American cuisine, doctors bemoaned the fact that people were not seeking medical treatment but were using useless or harmful herbs and concoctions. Laypeople sought self-reliance over “the establishment” with traditional natural products to achieve holistic mental and physical health.

The professional certification of Registered Dietitian became required by many states in the 1970s and 1980s. In 1973, the FDA required enriched or fortified foods to be labeled with ingredients and Recommended Daily Allowance values for protein and seven essential vitamins and minerals.

### Small-Scale to Global Mass Marketing

By the 1990s, as the counterculture matured, health-food issues saw compromise such as more integration of nutrition and preventative medicine in medical practice, or scientific evaluation of physiological properties in food beyond macro- and micronutrients. International conservation-development projects found wide use of herbal medicines to the extent that the World Health Organization promoted traditional medicine to cut health-care costs. The U.S. National Institutes of Health researched herbal medicine claims. A recent *Physicians’ Desk Reference* describes herbal uses and contraindications. FDA food label regulations gradually permitted scientifically tested nutrient content claims (for example, “low-fat,” “high fiber”), structure/function claims (for example, calcium aids in the growth and maintenance of bones), and a few health claims (for example, calcium reduces the risk of osteoporosis). In December 2000, the USDA defined national organic food standards to regulate health-food claims and to facilitate national and international trade. U.S. organic food sales increased from \$178 million in 1980 to \$1 billion in 1990 and \$7.8 billion in 2000 (Mergentine, 1994, p. 164; Myers and Rorie, 2000).

Natural product sales (including whole foods, organics, supplements, and household products) grew from \$1.9 billion in 1980, to \$4.2 billion in 1990, and to \$32 billion in 2000 (Spencer, 2001). Small cooperative health-food stores persisted, but large “one-stop” natural grocery stores opened in the 1980s and 1990s. Convenience attracted the “hippie” become “yuppie” professionals who retained health and environmental concerns but had little time to produce, obtain, or cook food. Mergers and acquisitions occurred as conventional food conglomerates bought out natural food product lines or whole companies. Regular chain grocery stores carried more organic foods besides conventional foods. The Internet provided both health-food magazine and retailer advertising as well as access to university and medical school websites. The Internet health-food market was initially profitable, but plateaued with delivery limited to nonperishables. Scientifically verified “functional foods” became popular, whether in regular meals, sports foods, or weight reduction. Consequently, antioxidants, fatty acids, phytoestrogens, flavinoids, pro- and prebiotics, are now promoted in a Functional Food Pyramid, mirroring the conventional USDA food pyramid adopted in 1992. Both nutrition education models acknowledge growing scientific evidence that fruits, vegetables, and grains are important to health, with lower emphasis on animal-derived food, compared to the Four Food Groups model used since 1958.

“Functional food,” “designer food,” and “nutraceutical” are used interchangeably. This is problematic in global trade regulation since food and drugs are compartmentalized differently in international regulatory agencies. Functional food is conventional food, but demonstrates physiological benefits and/or reduces the risk of chronic disease beyond basic nutritional functions. A nutraceutical is a product produced from foods but sold in pill, powder, and other medicinal forms not generally associated with food and demonstrated to have physiological benefit or provide protection against chronic disease (Stephen, 1998, p. 404). The American Dietetic Association classifies all food as functional at some physiological level, but suggests that “functional food” includes unmodified food as well as modified food. While some sports enthusiasts or dieters favor modified processed foods with higher nutrient content, many Americans and Europeans buy organic foods because they worry about allergic reactions and environmental hazards caused by genetic modification.

**HEARTH COOKERY.** The field of hearth cookery, in its most general sense, is immensely broad, encompassing standard kitchen practice from ancient human settlements to present-day cultures throughout the world. The twentieth century has seen the growth of this new study as historians and social and physical scientists worldwide have found it a source of illumination in traditional areas of research. Among them, one thinks of gender and work, family structure, economics and status, technology, ethnicity and acculturation, and health. Growing numbers of interdisciplinary publications attest to its value, as does its use in living history museums throughout the world. The traditional foods of the hearth have become fashionable in barbecue pits and smokehouses of both professionals and aficionados, in the recreated foods of brick-oven pizzas and artisanal bakeries, and in the restaurants of imaginative chefs using their dining-room fireplaces to simultaneously cook for their patrons and entertain them.

Reflector oven for open hearth cooking. Philadelphia, ca. 1855. Tin and cast iron. Joints of meat were roasted on the spit, which was turned by hand. In England, these implements were referred to as Dutch ovens. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

Despite vast differences between ethnic cuisines, this far-flung cookery practice may be described as a relatively simple array of basic cooking utensils used at a hearth, or fire-site. The hearth was usually situated at floor level and held the burning fuel (chiefly but not exclusively local wood); the flames, embers, and radiating heat did the work. More the exception than the rule, a few cultures developed convenient raised hearths, often built eighteen inches or so above floor level; despite this variation, the utensils and cookery principles remained the same. Where fuel was abundant, home brick or clay ovens were used as well. Until relatively recent innovations in fuels and technologies, hearth cooking was the predominant way (indeed, often the only way) of cooking.

### The American Hearth

American hearths have existed since the Stone Age in various degrees of modernization. Pre-Columbian Native American cookery sites were usually simple, their utensils often fashioned artfully from natural substances—wood, clay, stone, bone, shell, and hide. The family cooking site was generally out of doors and typically consisted of a flat stone-lined shallow pit, sometimes hold-

ing a small tripod of stones to support rounded clay pots or stone griddles. This was commonly augmented by deeper cooking pits in which food was buried for steaming, and with smoking and roasting racks of wood. Indoor cookery, appropriate for inclement seasons or for security, was a simplified version in which smoke escaped through the roof.

The earliest Europeans in the New World brought a working concept of the hearth that was in many ways similar and had in common frequent use of clay pots, tripods or legged trivets, large rounded forms, and flat griddles. Major differences were largely a consequence of the Old World metallurgy hitherto unknown in the Americas, and they added clear advantages of strength, transportability, durability, and more subtle heat transmission.

Seventeenth-century American colonists, following European architectural innovation, improved on their earlier floor fires and roof smoke holes by installing fireplaces with extended stone or brick hearths and chimneys. This new workspace was safer, more flexible, efficient, and comfortable, but hardly simple. As temperatures directly over the flames often exceed 600°F

## THE DUTCH OVEN

The history of certain pot forms is informed by early recipes. The following cooking directions seem to suggest an early Dutch oven, and what was also known as “bake kettle” technique.

“To bake an apple [egg] fritter” . . .  
place a little fire on the lid and let it bake this way.”

—*De Verstandige Kok* (The Intelligent Cook),  
Amsterdam, 1683

One hundred fifty years later, Mary Randolph described the use of a Dutch oven as a *bain marie* in her recipe:

“To Make Custards  
Fill the custard cups, put on the covers, and set them in a Dutch oven with water, but not enough to risk its boiling into the cups, Do not put on the top of the oven.”

—Mary Randolph, *The Virginia Housewife*, 1824,  
p. 180

(315°C), control of cooking temperatures was a technological challenge. Small three-legged clay, bronze, or iron pots were perched over small subsidiary fires or piles of glowing embers shoveled from the main fire onto the hearth. In addition, horizontal lug poles were installed high in the chimney; and from these hung iron trammels of several designs, their adjustable hooks capable of suspending pots at variable levels. The cook “turned” the temperature up or down by moving pots toward or away from the heat. In the early eighteenth century, innovative swinging cranes added the possibility of adjusting hanging pots and their contents without the work of lifting them.

### Fire and Heat Management

Hearth cooking was characterized not so much by the recipes, which varied widely according to time and place, as by general knowledge of fuels and heat regulation and the maintenance of steady heat in the face of ever-changing temperatures. Fires waxed and waned as fuels ignited, blazing up into flames, and then subsided into glowing coals or embers. Good cooks used this varying heat to advantage, shifting pots according to the state of the fire and the needs of the dish. For example, when boiling water, one hung the kettle close to the hottest flames, but when warming milk (which burns easily), one set the pot on the hearth away from the scorching tem-

peratures and, along with stirring, may have rotated it 180 degrees periodically for even cooking.

The experienced cook judged cooking temperatures with sensory clues—visual, auditory, olfactory, and tactile. Heat was estimated repeatedly through the cooking processes by holding one’s hand between the fire and the pot, by the sounds of frying or boiling, and by the appearance of the coals.

### Fuels

Fire temperatures were regulated by the choice of fuel. Most pine burns cool; osage orange and sassafras are very hot. Hard woods (for example, hard maples, oak, fruit, or nut), aged and split, were most desirable, but not without cost. In the American colonies, where wood was often abundant, firewood production demanded long hours invested in felling trees and then cutting, hauling, splitting, and stacking. Yet even with this apparently unending richness, there were places where people were forced to cook over peat (by the mid-eighteenth century, Long Island had depleted its forests) or buffalo chips (the prairies). These situations paralleled those of Ireland, India, China, and nomadic Asia, where similar substitutions were necessary. Consequently, the roaring kitchen fire, a necessity for producing beds of coals, was desirable but not always standard. Wood for cooking fires was sometimes conserved by fine splitting, which had added advantages of efficiency, faster ignition, and more responsive heat replenishment. In combination with flames and embers, assorted sizes of wood enabled the cook to prepare a number of dishes at one time, each pot at its most appropriate temperature.

In maintaining desired warmth, a variety of techniques involved adding, removing, and resituating fuel. For example, a log set into the flames creates a temporary barrier and a cool spot above it; but as it catches fire, it creates a hot spot. Similarly, enlarging the air channels inside the fire increases its rate of burning, while consolidating the fuel and cutting off air supply slows it down.

### The Pots

The pots and their technologies were also players in temperature maintenance. Colonists imported or manufactured the designs from home that traditionally worked well with fire, and incorporated special features that added to their effectiveness. Some pots had their own legs for straddling the coals, or used high cooking trivets for that purpose. Larger kettles also incorporated swinging bale handles that hung them from a trammel and crane S-hooks. Many had rounded or bulbous bottoms that transmitted the heat evenly, without the angular corners in which food could burn. Their long handles allowed the cook to avoid the blasting heat of the central fire, as did a variety of long-handled forged hand utensils (spoons, ladles, skimmers, turners, forks, etc.). Like European antecedents, they were made of iron, brass, bell-metal, copper, tin, and ceramics. One New World

adaptation, the cast-iron “American Dutch oven,” boasted a heavy deep-rimmed lid to hold coals above and three stilt legs to straddle coals below.

Basic *batteries de cuisine* included assorted cast-iron kettles, water kettles, spiders (frying pans), posnets (saucepans), and griddles, as well as open kettles and pans of cast brass or bell-metal. These heavy pots worked well with wet cooking techniques. However, for dry-heat cookery and high-temperature processes such as frying and broiling, hand-forged metals, being better conductors, were formed into spiders (frying pans) and gridirons (broilers). Tin reflecting ovens made superlative roasters. An array of these pots was common in middling or average kitchens. One’s economic status was reflected in the range of utensils: where less fortunate families were perhaps limited to a cooking kettle, water kettle, and frying pan, privileged families owned larger assortments and varied sizes of the basics, supplemented with specialized equipment such as wafer irons, chafing dishes, mounted clock jacks to turn roasts on heavy spits, decorative copper or ceramic molds, or hand-forged geared grinders.

### The Cuisine

Cooking with fire has always had the potential for both simple and complex cuisines. The simple hearths of remote and rural areas or those of people of modest means have produced the one-pot dishes (simmered soups, porridges, or stews), roasted meats, and simple baking that have been the mainstay of daily cooking everywhere. At the other extreme are the culinary heights of the Roman and Ottoman empires, Persia, India, China, Mexico, France, and Italy, in which simple equipment and fuel have been no obstacle to fine sauces and elaborate confections. The early introduction of bronze and iron utensils in wealthier and more cosmopolitan urban civilizations enlarged the range of their hearths, enabling such possibilities as the high-temperature deep-fried *kunafa*, a crisp medieval Arabic bread. To this day, the hearth remains the center of food preparation in both primitive and modernized homes throughout the world and figures in such basic preparations as lightly crisped, griddle-baked Mexican tortillas or Moroccan flatbreads.

The average colonial American cook of moderate means had the skills and resources to turn out complex family meals, undaunted by fire-tending, stooping to floor or crane levels, and relatively primitive equipment. Her success actually had little to do with hearth limitations, depending more on the time of year and seasonal homegrown food availability, on access to imported ingredients (in particular, sugars, spices, and other flavorings), and on the amount of time and help she had for preparations. Seventeenth- and eighteenth-century European cookbooks used in the colonies show a wide array of recipes and varied techniques, among them boiling, simmering, roasting, frying, sautéing, fine baking, preserving, and candying.

### FIRESIDE COOKERY

The following is a selection of wonderful recipes from the original eighteenth- and nineteenth-century sources:

#### *Batter Cakes*

“Boil two cups of small hominy very soft and add an equal quantity of corn meal with a little salt, and a large spoonful of butter; make it into a thin batter with three eggs, and a sufficient quantity of milk, beat all together some time, and bake them on a griddle or in waffle irons . . .”

—Mary Randolph, *The Virginia Housewife*, 1824, p. 171

#### *Wafers*

“Make a very thin batter with eggs, milk, butter, and powdered loaf sugar, to your taste; pour it into wafer-irons, bake them very quick, without browning; roll them as you take them from the irons.”

—Mary Randolph, *The Virginia Housewife*, 1824, p. 173

Not all fireside cookery was that simple. This somewhat more complex dish was offered by Hannah Glasse’s *Art of Cookery*, 1747.

#### *A Jugged Hare*

“Cut it in little Pieces, lard them here and there with little Slips of Bacon, feafon them with a very little Pepper and Salt, put them into an earthen Jugg, with a Blade or two of Mace, an Onion ftuck with Cloves, and a Bundle of Sweet Herbs; cover the Jugg or Jar you do it in, fo clofe, that nothing can get in, then fet it in a Pot of boiling Water, keep the Water boiling, and three Hours will do it, then turn it out into the Dift, and take out the Onion and Sweet Herbs, and fend it to the Table hot.”

—Hannah Glasse, *The Art of Cookery*, 1747, p. 50

By all historical accounts, among them Karen and John Hess’s *The Taste of America*, and the experiences of such food historians as Sandra L. Oliver in recreating these recipes today, the food of accomplished early cooks met the highest standards of the modern palate. For example, roasting even unseasoned fowl and red meat in an open tin reflecting oven set against the fire produced a product far superior to that of its modern gas or electric counterpart. The technique produced a juicy and tender texture, good crust or skin, and slight smokiness, and generally enhanced natural flavor. Likewise, one’s daily cornbread, prepared in a heavy Dutch oven, boasted

## KITCHEN EQUIPMENT

The nineteenth-century overlap of hearth and cookstove technologies is most apparent in early trade catalogs. For example, *Catalogue of Savery & Co.'s Castings* (Philadelphia: circa 1855) offered assorted stovetop griddles and kettles (flat bottoms, no legs), and various three-legged hearth pots such as skillets, griddles, kettles, Dutch ovens, and spiders (pp. 4–25).

delicate moistness and a wonderful crust unequaled in modern ovens.

### American Hearth-to-Cookstove Transitions

In the 1790s, when over 90 percent of Americans were farming, hearth cooking was the sole means of meal preparation in both countryside and city. With the growth of cities in the nineteenth century and the gradual introduction of cookstoves, it survived in closest association with rural life. The new cookstove, developed and popularized in growing cities by 1850, presented a major force in women's changing social roles and the cuisine, but for many years kitchens reflected an overlap in the use of these technologies. Well into the twentieth century there were still communities, notably in remote areas of Appalachia, where hearth cookery sustained life.

The earliest kitchen hearths were associated with relatively small homes in which they were the focus of the house, and the center of much work and socializing. They offered not only cooking heat, but also a warm winter-time house. In time, and with the trend to enlarging American homes, they were distanced from expanded specialized dining and living rooms. At times they were relegated to a separate building (especially in the South and on wealthy farms or plantations), as families sought to remove themselves from the sounds, smells, and dangers of the work. The passing of the hearth in favor of the cookstove was not always lauded; some average families mourned the loss of the congenial kitchen fireside, fearful that both the cuisine and the family were doomed.

### Social Implications

The experience of contemporary hearth cooks has added to the correction of past assumptions and misconceptions; for example, the experienced home cook could indeed produce delicious complex meals on a daily basis. There was no inherent danger in long clothing—to the contrary, the natural fibers did not flame (only smolder), while skirts and sleeves provided comfort, insulating the body from the heat. There was more threat from tipped kettles and scalding.

In addition, the activity has reinforced the concept of a strong family unit: despite gender work divisions, there were clear advantages to social cooperation—the quality and quantity of family food depended on it. The large body of economically viable skills and knowledge that were specifically women's, the oral tradition of recipe and cookery transmission, the time and strength required, the daily distinctions between drudgery and creativity, and the need to juggle hearth tasks with other necessary chores are only some of the areas informing the current interpretation of social history.

If nothing else, in pinpointing individual and family behavior, it supports a strong case for individualization that surviving cooking manuscripts do not convey.

**HÉDIARD, FERDINAND.** Born in Loupe, a village near Chartres, Hédiard (1832–1898) became interested in the world of imported foods at a young age when he discovered at the port of Le Havre all kinds of cargo from Martinique, Haiti, Guadeloupe, and the Lesser Antilles, all part of the colonial French empire at the time. Fired with the mission of introducing the French to the food wonders he had experienced as a young boy, he opened his first store at the age of twenty-three, in 1850. In 1854, he opened a larger store, which he called "Comptoir d'épices et des Colonies," (trading post selling the products of the colonies), in effect, the first French grocery store. He imported island commodities such as rum, cacao, coffee, bananas, and other tropical fruits and made them all available to a public—including the painter Eugène Delacroix, who lived in the neighborhood—that had never experienced such a taste of the exotic.

As the French empire expanded, Hédiard's business grew. He made a big splash exhibiting the pride of his importations at the 1867 Paris World's Fair, and in 1880 he opened another store in Paris, much more fully realized than the first, at 21 place de la Madeleine, where the flagship store still stands. In 1889, he penned a book of recipes (still in print) to show off the best use of his exotic products. Over its long history, the store has drawn the notice of the rich and famous, such as the writers Alexandre Dumas, Colette, and Jean Cocteau; performing artists such as Jean Gabin, Marlene Dietrich, and Charlie Chaplin; and a loyal following of princes, maharajas, and politicians.

Upon his death, he left the business to his daughter Marie-Blanche and her husband, Max Kusel, who operated it for a time, after which a series of owners have continued the operation in expanded but somewhat changed form.

In 1920, the store's pastry chefs developed a special line of marzipan candies. In 1935, what became the store's signature gold-foil-wrapped packages were developed. The store was modernized in 1950. In 1969, to handle the growing demand worldwide for the Hédiard line, a facility near Nîmes in the Gard Valley opened for the artisanal production of jams, conserves, fruit pastes, glacéed fruits, and other products. Expansion to five additional city locations throughout Paris and three locations in the

suburbs followed in the 1970s. To commemorate the 150-year anniversary, a restaurant was opened at the place de la Madeleine location. Since 2001, an Hédiard website is bringing the world to Hédiard—not bad for a company founded by a man who never left French soil.

**HERBICIDES.** Weeds have been deemed undesirable during much of human history for their negative influence on crop production, their unsightly appearance in the landscape, and in some cases their toxic properties and negative effects on human and animal health. Consequently, weed control is as old as the discovery of agriculture, eight to ten thousand years ago. Techniques for weed control have progressed from the employment of intensive human labor to complex systems involving mechanical, chemical, and biological methods. The earliest methods to eliminate weeds involved physical removal by grubbing or hoeing, followed by cultivation practices using first draft animals and then tractors. Since 1945, the use of chemical herbicides has become the predominant weed control technique in many parts of the world.

Chemicals have been suggested for weed control since antiquity. Theophrastus (372–287 B.C.E.) mentions killing trees by pouring olive oil over their roots. Cato (234–149 B.C.E.) advocated the use of amurca (the watery residue left after the oil is drained from crushed olives) for weed control. Other chemicals include sodium chloride, sulfuric acid, sodium arsenite, copper sulfate, iron sulfate, carbon bisulfate, arsenic trichloride, and petroleum oils. The first synthetic herbicide, 2-methyl-4,6-dinitrophenol (dinitro) was developed in France in 1932 for selective weed control in beans. In 1940 ammonium sulfamate was introduced for control of woody plants.

The chemical herbicide age began in 1941 when R. Pokorny first synthesized 2,4-dichlorophenoxy acetic acid (2,4-D) and reported that it had growth-regulating effects on plants. E. J. Krause of the University of Chicago later suggested that 2,4-D might be used to kill weeds, which stimulated research to test this and other newly synthesized chemicals for weed control in the field. These herbicides proved effective, and in 1945 the American Chemical Paint Company was awarded a patent for 2,4-D as a weed killer. The great potential of synthetic herbicides to control weeds and reduce human labor stimulated the birth of the herbicide chemical industry,

resulting in the development of over 180 herbicides for weed control by the end of the twentieth century.

Herbicides are now primarily developed in the private sector. Chemists typically synthesize a variety of compounds, which are screened for their ability to control weeds and then modified and formulated for efficient use. Present herbicides tend to have very low mammalian toxicity because they inhibit biochemical pathways that are unique to plants.

There are a number of chemical classes of herbicides and various mechanisms by which herbicides kill plants. Herbicides generally act by inhibiting specific cellular functions, including photosynthesis, plant-specific amino acid biosynthesis, pigment formation, shoot and root growth, cell membranes, cellulose biosynthesis, lipid biosynthesis, and growth hormone activity.

Herbicides may be applied in many ways. Some herbicides are applied to the soil and absorbed by the plant root and/or shoot and move to their site of inhibition within the plant. Others are primarily applied to emerged foliage and either have an immediate contact effect on the foliage by burning or desiccation, or are translocated throughout the plant, leading to total plant death (systemics). Most soil-applied herbicides kill weed seedlings as they emerge from the soil, while foliage-applied herbicides control emerged weeds and can kill quite large plants.

Herbicide selectivity, the ability to kill weeds but not crops, can be accomplished either by directed application or through biochemical mechanisms. Placement of the herbicide to avoid contact with the crop is widely used. For example, tree crops with deep roots often do not absorb soil-applied herbicides. While it is an effective herbicide for killing most broadleaf plants (dicots), 2,4-D is ineffective on most grassy weeds (monocots). This makes it useful in monocot crops, such as grains and turf. Others selectively kill monocot grasses but not dicots, making them effective in crops such as soybean. Some crops metabolize an applied herbicide to an inactive form while the weeds cannot, so the weed is killed, but the crop is not harmed. For example, atrazine is metabolized to an inactive form by maize while weeds are killed.

In many weed and crop situations there are no good selectivity mechanisms for herbicides. With the advent of recombinant DNA technology (genetic engineering) certain crop plants, such as soybean, corn, and cotton, have been made resistant to nonselective herbicides such as glyphosate by adding genes that make the crop immune to the herbicide. This technology is expected to increase, though its rate of acceptance has been slowed by the reluctance of the food industry to utilize transgenic crops because of concerns expressed by certain consumer advocacy groups.

Modern agriculture in the United States is almost inconceivable without the use of herbicides. Herbicides reduce labor inputs for weed control and make it possi-

ble to control weeds where cultivation is infeasible. They reduce the need for mechanical cultivation that can injure crop plants and lead to soil degradation via structure loss and compaction. Herbicides allow the use of no-till crop production, which reduces the need for plowing, now considered a destructive practice. Efficient weed control improves crop growth by reducing weed competition for nutrients and water, and results in improved harvesting and crop quality.

### **A Source of Controversy**

Despite the obvious advantages of herbicides, their use has raised concerns relating to human health and the environment. Since herbicides are toxic to plants, critics have questioned their toxicity to other organisms exposed directly or indirectly. The persistence of some herbicides in the environment has led to concerns relating to their carryover in the soil and effects on subsequent crops as well as their influences, due to drift or volatilization, on non-target plants. Furthermore, through repeated exposure to herbicides, many weeds have become resistant, which reduces the efficacy of previously effective herbicides.

Other concerns involve herbicide costs, the requirement for additional equipment for precision application, and questions relating to proper disposal of unused herbicides.

The advantages and disadvantages of herbicide use are thoroughly evaluated by the U.S. Environmental Protection Agency (EPA) prior to registration and labeling of any new compound. All new pesticides must be granted a registration, permitting their distribution, sale, and use. The EPA assesses a wide variety of potential human health and environmental effects associated with use of the product, including the particular site or crop on which it is to be used; the amount, frequency and timing of its use; and recommended storage and container disposal practices.

In evaluating a pesticide registration application, the registrant must provide data from tests done according to specific EPA guidelines conducted under recognized "Good Laboratory Practice." Results of these tests determine whether a pesticide has the potential to cause adverse effects on humans, wildlife, fish, or plants, including endangered species and non-target organisms, as well as possible contamination of surface water or groundwater from leaching, runoff, and spray drift. The potential human risks evaluated include short-term toxicity and long-term effects, such as cancer and reproductive system disorders. A pesticide will only be registered if it is determined that it can be used to perform its intended function without unreasonably adverse effects on applicators, consumers, or the environment. The EPA also must approve the specific language that appears on each pesticide label; the product can only be legally used according to label directions. The EPA continually evaluates herbicides as to their safety, and any compound that is found to cause any adverse effect is immediately removed from the market.

At the present time herbicides provide consistent, broad-spectrum, and effective weed management in an economical manner. In the future, herbicides will be required to pass even more stringent tests related to their safety. While new-generation herbicides will likely be applied at even lower doses with less environmental persistence and exceedingly low toxicity to non-target organisms, herbicides are now recognized as only one factor in efficient weed control. Weed management is an ever-evolving system that will continue to use an integrated approach, combining cultural, mechanical, chemical, and biological techniques. In this process, however, herbicides will remain an essential component for weed control to help insure a sustainable food production system that reduces unacceptable risks to the environment while producing an abundant and safe food supply.

**HERBS AND SPICES.** The terms “herb” and “spice” describe plants or parts of plants used for medicine, cooking, and pleasure all over the world. These plants number in the thousands and come from almost every plant family known. This makes it almost impossible to generalize about their uses and properties. However, a treatment of this length could not be written without generalizations, so it is important to keep in mind that for every statement made one or more exceptions exist.

#### Definitions

Herbs are the green, leafy parts of plants. They are most efficacious and flavorful when used fresh, and they are mostly grown in temperate to hot regions. Spices are derived from any part of a plant that is not a leaf: for example, cloves are flower buds, cinnamon is bark, ginger is a root, peppercorns are berries, nigella is seed, cumin is a fruit, saffron is stigmas, cardamom is pods and seeds, and asafetida is a gum. Spices are usually used in small amounts, are best used dry (the drying process often enhances the flavor), and most grow in subtropical or tropical climates. One single plant can be both an herb and a spice. Aromatic seeds like dill are a spice, while dill leaves are an herb. However, coriander and hamburger parsley roots, garlic and fennel bulbs are all regarded as herbs rather than spices.

#### What Do They Look Like?

Herbs and spices cover the complete range of growth habits and sizes of plants, and they can be annuals, biennials, perennials, trees, shrubs, climbers, and grasses. They grow in a wide range of conditions and habitats from the tropics to polar regions. They can be found at sea level, some even grow in the sea or in fresh water, and others grow near the tops of the highest mountains. Despite this diversity it is true that many of the better-known herbs and spices fall into distinct groups. One group contains those plants found in the Lamiaceae (mint family). They are characterized by young stems that are four-angled, simple opposite leaves, and flowers with five more or less fused petals. Glands on these plants usually contain volatile fragrant oils. Most originate in the Mediterranean or Central Asia and are used as potherbs, to make perfumes, and in the manufacture of pharmaceutical products. Well-known herbs such as basil, bergamot, calamint, hyssop, lavender, lemon balm, mint, rosemary, sage, savory, and thyme are in this family.

In the Apiaceae (carrot family) are important herbs and spices such as angelica, anise, caraway, chervil, coriander, cumin, dill, fennel, gotu kola, lovage, and parsley. These plants mostly originate from temperate regions all over the world. They are characterized by being aromatic and having hollow stems and dissected leaves arranged in spirals, often attached by a base that sheathes the stem. The usually small, five-petaled flowers appear in umbels and are followed by strongly scented fruits (often called seeds). The leaves of many of these plants are important herbs, while the fruits are widely used spices.

French tarragon is in the Asteraceae (daisy family), members of which grow mostly in temperate regions all over the world. Plants in this group usually have simple or dissected leaves arranged in spirals. Flowers are usually tiny discs grouped together in compact heads and surrounded by a ring of ray flowers with straplike petals. Other herbs in this family include burdock, chamomile, chicory, dandelion, marigolds, pyrethrum, safflower, wormwood, and yarrow. Some are important culinary herbs, while others are important medicinal herbs. The group also includes herbs used to kill and repel insects and to produce dyes.

The Lauraceae (laurel family) consists mostly of aromatic, evergreen shrubs and trees originating from warm and tropical regions of Southeast Asia and northern South America. The herbs and spices in this family include sweet bay, camphor, cassia, cinnamon, and saffrafras.

Allspice, cloves, cajuput oil, eucalyptus, and myrtle are all in the Myrtaceae (myrtle family). These are trees and shrubs that grow in tropical and warm areas of the world. They bear scented leaves containing important essential oils, and many also bear edible fruit.

Some important root spices are in the Zingiberaceae (ginger family). These plants mostly grow from thickened

aromatic rhizomes with large, upright, alternate leaves. They are mostly found in tropical and subtropical regions of the world. In this family are cardamom, Chinese keys, galangal, gingers, torch ginger, turmeric, and zedoary.

### History

Archaeological evidence shows that the use of spices and herbs dates back to long before recorded history, when human ancestors first added sharp-flavored leaves to early cooking pots. Roaming hunter-gatherer groups experimented with leaves, roots, flowers, and seeds, so over time they built up a precious compendium of knowledge that was passed from one generation to the next. As civilization progressed and nomadic tribes settled in one place, herbs and spices were not just collected from the wild but were deliberately sown near dwelling places. By the beginning of the agricultural period plants were collected from the wild and grown near dwellings for food, flavor, medicine, fuel, decoration, dyes, poison, and weapons and to alter early humans' sense of reality.

The earliest written records come from ancient Egyptian, Chinese, and Indian cultures. The Ebers Papyrus that dates from 1550 B.C.E. describes some eight hundred different medicinal remedies and numerous medicinal procedures. Early Egyptians used spices and herbs in medicine, as cosmetics and perfumes, for embalming, in cooking, and to kill and repel pests.

### Trade

The ancient trade in some spices was highly lucrative. Black pepper was the most lucrative of all, although cassia and cinnamon were essential ingredients in Egyptian embalmment. Taprobane (Sri Lanka) was well known to the Greeks and Romans, and trade with it is described in

the Byzantine topography of Cosmas Indicopleustes. The earliest known Chinese records of the uses of plants date from 2700 B.C.E., from the herbal compiled by Emperor Chin Nong. In India the Vedic literature of about 1500–1200 B.C.E. describes many different plants used in religious ceremonies. When the Queen of Sheba visited King Solomon in the tenth century B.C.E., she offered gifts of rare and sought-after spices and herbs, probably with the hope of increasing and expanding the existing trade in these commodities.

Evidence of trading and use of herbs and spices is in the writings, among others, of the Greek physician Dioscorides and the Roman civil servant Pliny the Elder in the first century C.E. The spread of the Roman Empire also spread herbs such as rosemary, savory, garlic, and thyme into northern Europe and Britain. Romans took with them precious supplies of spices like pepper and ginger. The fall of the Roman Empire accompanied a dramatic decrease in trade until the eighth century and the spread of the Muslim Empire, when once again spices and herbs were on the move and were widely used in medicine and cooking. After the Norman conquest of Britain, spices such as ginger, cloves, mace, and pepper were once again found on the tables of wealthy Britons.

Later the ongoing search for and trade in other valuable spices, which at different times have been worth as much as gold, led to some of the great voyages of discovery. Ginger, pepper, cloves, cinnamon, galangal, mace, and nutmeg were the reasons for battles fought, fortunes made and lost, and new worlds discovered. These spices launched Europe and Britain, attempting to satiate their desires for these exotic ingredients, into the age of exploration. Christopher Columbus discovered America while searching for a new sea route to the Spice Islands. In 1498 Vasco da Gama, the Portuguese navigator, rounded the Cape of Good Hope and established a new spice route to India and beyond. Magellan eventually found the western route to the Spice Islands in the 1520s. In the following centuries the Portuguese, Dutch, and British fought wars for control of these routes and the islands where many of the spices grew.

Modern methods of preservation led to a decrease in the use of spices in many Western countries, and at the same time, with modern methods of transportation, spices became ubiquitous and relatively cheap.

### Growing Herbs and Spices

In the past herbs and spices were grown in gardens and harvested for use in the home, or they were collected from the wild, in what was known as wild crafting. As the demand for herbs and spices increased, they were also grown on a small scale as agricultural crops. The growth, harvest, and processing of herbs and spices was and in many cases has remained a labor-intensive enterprise. Consequently these crops often were grown in countries where labor was cheap. In the early twenty-first century Egypt grew and exported large quantities of anise, basil,

TABLE 1

## Common culinary herbs

Name*	Description	Climate, place of origin	Part used	Uses
Basil <i>Ocimum</i> species Lamiaceae	Annual, small shrub	Tropical to warm temperate, Asia and Africa	Fresh leaves, young stems	Tomato dishes, salad, stuffings, sauces, soups
Bay leaves <i>Laurus nobilis</i> Lauraceae	Perennial, medium tree	Temperate, Mediterranean	Fresh or dried leaves	Soups, stews, stir-fries, sauces, meats, desserts
Bergamot <i>Monarda didyma</i> Lamiaceae	Herbaceous perennial, medium	Temperate, North America	Fresh or dried leaves and flowers	Salads, pork, chicken, seafood, eggs, drinks, teas
Chervil <i>Anthriscus cerefolium</i> Apiaceae	Annual, small shrub	Temperate, Europe and Western Asia	Fresh leaves	Salads, stir-fries, sauces, cheese, garnishes
Chives <i>Allium shoeprasum</i> Alliaceae	Herbaceous perennial, small clumps	Cold temperate, Yugoslavia, Siberia, Asia Minor	Fresh and dried leaves and flowers	Salads, stir-fries, sauces, cheese, breads, garnishes
Cilantro <i>Coriandrum sativum</i> Apiaceae	Annual, small shrub	Temperate, Europe	Fresh leaves, flowers, roots, dried seeds	Salads, stir-fries, soups, chicken, fish, eggs, garnishes
Curry leaf <i>Murraya koenigii</i> Rutaceae	Perennial, small tree	Tropical and subtropical, Asia	Fresh and dried leaves	Curries, pickles, chutneys, fish, vegetables, rice
Dill <i>Anethum graveolens</i> Apiaceae	Annual, tall shrub	Temperate, Southwest Asia	Fresh and dried leaves, dried seeds	Salads, stir-fries, chicken, seafood, sauces, garnishes
Fennel <i>Foeniculum vulgare</i> Apiaceae	Herbaceous perennial, tall shrub	Temperate, Mediterranean seeds	Fresh and dried leaves, fresh stem base, dried seeds	Salads, stir-fries, eggs, seafood, sauces, soups, vegetables
Garlic chives <i>Allium tuberosum</i> Alliaceae	Herbaceous perennial, small clump	Temperate, Southeast Asia	Fresh leaves flowers, buds, flower stems	Salads, stir-fries, sauces, soups, cheese, garnishes
Gotu kola <i>Centella asiatica</i> Apiaceae	Perennial, low spreading groundcover	Tropical to warm temperate, Asia and Australasia	Fresh leaves	Salads, soups, rice, garnishes
Lemongrass <i>Cymbopogon citratus</i> Poaceae	Perennial, clumping grass	Tropical to warm temperate, India and Ceylon	Fresh and dried leaves and stems	Soups, stir-fries, beef, chicken, seafood, sauces, teas
Marjoram and oregano <i>Origanum</i> species Lamiaceae	Herbaceous perennial, spreading clumps	Temperate Mediterranean to East Asia	Fresh and dried leaves	Soups, stews, sauces, cheese, breads, eggs, vegetables
Mint <i>Mentha</i> species Lamiaceae	Herbaceous perennial, spreading clumps	Temperate, Europe, Asia, Africa	Fresh and dried leaves	Salads, sauces, lamb, chicken, seafood, garnishes, drinks, teas
Parsley <i>Petroselinum crispum</i> Apiaceae	Biennial, low-growing clump	Temperate, Europe	Fresh and dried leaves	Salads, sauces, cheese, garnishes on most foods
Rosemary <i>Rosmarinus officinalis</i> Lamiaceae	Woody perennial, medium bush	Temperate, Mediterranean	Fresh and dried leaves	Stews, sauces, soups, stuffings, breads, eggs, teas
Sage <i>Salvia officinalis</i> Lamiaceae	Woody perennial, medium bush	Temperate, Mediterranean and North Africa	Fresh and dried leaves	Stews, sauces, soups, stuffings, breads, eggs, teas
Tarragon <i>Artemisia dracunculus</i> Asteraceae	Herbaceous perennial, spreading clump	Temperate, Central and Eastern Europe, Southern Russia	Fresh and dried leaves	Salads, soups, stews, chicken, seafood, eggs, vegetables
Thyme <i>Thymus</i> species Lamiaceae	Perennial, low bush or spreading clump	Temperate, Europe and Asia	Fresh and dried leaves	Stews, sauces, soups, stuffings, breads, eggs, teas
Watercress <i>Nasturtium officinale</i> Brassicaceae	Perennial, spreading clump	Temperate, Europe and Southwest Asia	Fresh leaves	Salads, soups, sauces, eggs, garnishes

\*Garlic is not included here as it is discussed in the text.

Fresh nutmegs are red. The shell covering is dried and called mace. © BOB KRIST/CORBIS.

caraway, dill, and fennel; China produced fennel, garlic, ginger, and cumin; India grew celery seed, fennel, and turmeric; and Croatia produced sage, savory, and rosemary, to name a few. At that time the herb and spice industry could be divided into three main categories, essential oils, medicinal crops, and culinary herbs and spices (fresh and dried).

### Essential Oils

Essential oils are usually found in specialized oil cells or ducts in plants. Oils from aromatic plants are generally volatile, so they are extracted by water or steam distillation. Some volatile and most nonvolatile essential oils are obtained by solvent extraction. The aromatic, resinous product obtained from nonvolatile oils is known as an oleoresin. Oleoresins are concentrated and are widely used in the food industry. For example, pepper oleoresins are used in processed food, while turmeric oleoresin is a common natural coloring agent in food and pharmaceuticals. Essential oils are produced and processed all over the world, and France, Brazil, China, Spain, and Mexico are among the largest producers. These oils are often the by-products of another industry, and citrus oils, extracted from the skins of oranges, lemons, and limes, account for a large proportion of the essential oil industry. Pine and cedarwood oils are by-products of the timber industry. Of the herbs and spices planted specifically for oil production, anise, bergamot, citronella, lemongrass, lavender, mints, and rosemary are probably the most widely grown. Mints represent the largest essential-oil crop in the United States. Dill is also an important oil crop, used mostly in the manufacture of pickles.

### Medicinal Herbs and Spices

It is particularly important that medicinal herbs and spices are grown in ideal rather than marginal conditions so the proportion of medicinal constituents is maximized.

Usually the constituents of medicinal value to humans are secondary metabolites produced by plants for purposes other than growth. Advocates for organic gardening insist that conditions most closely approximating wild conditions are best for growing herbs, especially medicinal herbs, because the use of pesticides and herbicides can alter the plants' constituents, thereby altering their flavors and medicinal attributes.

### Wild Herbs and Spices

Wild crafting of herbs and spices occurs all over the world. Some herbs, such as echinacea and goldenseal, have become rare in the wild because of overharvesting. Although all herbs can be cultivated, one school of thought says the best medicinal herbs are taken from the wild, so pressure on wild herb populations in all parts of the world continues. Conversely, some cultivated herbs have escaped into the wild, where they have become problem weeds. Harvesting these from the wild helps keep them under control while providing plenty of raw material for processing.

### Culinary Herbs

In the past culinary herbs and spices were collected from the wild or grown in gardens among vegetables and flowers. By the twenty-first century, although the traditions of collecting flavorings from the wild and growing a few herbs in gardens continued, more people in Western countries demanded interesting and exotic flavors with their foods. This trend produced a proliferation of fresh, processed, frozen, and dried herbs and spices on supermarket shelves and a burgeoning industry to support these demands. In these Western countries the processed herb market is mostly supplied by companies that dry, process, package, and transport the produce to market. These companies are usually supplied by contract growers, often from other countries. Many herbs are dried for use as herb teas as well as for flavorings. A smaller but increasing market exists for biodynamically and organically grown herbs, both dried and fresh.

### Culinary Spices

Most commercially grown herbs are produced in temperate regions, as are the seed spices, such as coriander, dill, cumin, caraway, and fennel. Most spices, however, are indigenous to and are grown commercially in subtropical and tropical regions. Each spice is usually grown in just a handful of countries and then exported all over the world. For example, the best cinnamon still comes from its native Sri Lanka; cassia come from China, Indonesia, and Vietnam; cloves come from the Moluccas, Zanzibar, and Madagascar; pepper comes from India, Indonesia, and Malaysia; and ginger comes from Jamaica, Nigeria, and India. The spice saffron is native to more temperate regions, and most of it is grown in and exported from Spain, Kashmir, Greece, and Iran.

## Drying Spices

Spices are usually dried straight after harvest, either in the sun or in drying rooms. The drying ensures that essential oils and oleoresins are largely preserved intact. As some spices dry, enzymes and chemicals in the spice react to create a different flavor. For example, when peppercorns are dried in the sun, the volatile oil piperine is formed, thus giving dried peppercorns their unique flavor. Vanilla beans also only develop their flavor after months of careful, slow drying. Once dry, spices are best stored in airtight containers to preserve their volatile oils. These oils are released by the application of heat (frying, roasting, boiling) and are absorbed by the food, which takes on a new flavor. Many spices are ground after drying. But once they are ground they lose their flavor much more quickly, so it is best to use freshly ground spices when possible. Whole spices can be stored away from direct light for up to three years, ground spices only for about one year.

## Fresh Herbs

The fresh herb market in Western countries saw enormous growth in the last decade of the twentieth century with an increase in the variety of herbs available for purchase. As the size of this market increased, some herbs moved from a niche product to one fully integrated with fresh market vegetables, so they are grown, harvested, packaged, transported, and marketed in the same way as vegetables. Even so, fresh herbs tend to be grown on smaller farms and are often sold in smaller specialty grocers, farmers' markets, and roadside stalls. In the supermarkets fresh herbs, often hydroponically grown in greenhouses, are sold in bunches or increasingly in pots. At the beginning of the twenty-first century the fresh herbs available for sale at the Los Angeles wholesale fruit and vegetable market included anise, arugula (rocket), basil, chives, cilantro, dill, epasote, lemongrass, marjoram, mint, oregano, parsley, rosemary, sage, sorrel, tarragon, thyme, and watercress. The variety of herbs available is increasing with demands from immigrants for herbs from their native countries and a general wish for a greater variety in herb flavors.

## Everyday Ingredients

Most people eat or use herbs and spices in some form every day, in vanilla ice cream, chili and Worcestershire sauces, alcoholic drinks such as gin, in cinnamon buns and in seed breads. Herbs flavor toothpaste and cough medicines, and they are drunk as teas and added to vinegars, oils, and sauces. The scents and flavors of herbs and spices originate from the essential oils in the plant material. These oils are a complex combination of organic compounds such as alcohols, esters, and aldehydes. So the growth, harvest, and drying of herbs and spices aims to maximize the preservation of these oils and thereby the scents and flavors. This is also true of the preparation and cooking of herbs and spices. For maximum flavor herbs should be harvested at the last possible moment

## CLASSIC HERB COMBINATIONS

### *Bouquet Garni*

This name is given to any small bunch of fresh herbs tied together and added to sauces, stock, soups, stews, and casseroles. The herbs are removed before serving. The basic combination is one bay leaf, a sprig of parsley, and a sprig of thyme. Other herbs used in bouquet garni are lemon balm, tarragon, fennel, rosemary, sage, and oregano.

### *Fines Herbes*

A classic French combination of equal amounts of finely chopped chervil, chives, parsley, and tarragon. This mixture is used with soups, sauces, eggs, grilled meats, and fish. Lovage and fennel are sometimes added.

### *Herbes de Provence*

A mixture of herbs that thrive in southern France during the summer: marjoram, oregano, rosemary, savory, and thyme. Use fresh or dried on any Mediterranean-style dish, pizza, stew, kebabs, and tomato dishes.

and chopped just before use. If this is not possible, purchased herbs should look as fresh as possible (no wilting or bruised or brown leaves) and should be stored in plastic bags in the refrigerator until needed, preferably not more than a few days. Again they should be chopped just before use.

## Dried Herbs

Dried herbs should be green (not brown) and should retain a lot of flavor when crushed. They should be purchased in small amounts and used before the use-by date. Drying an herb or spice reduces the water content, and if done properly it concentrates the flavor. For this reason using only a quarter to a third of what one would use if the herb were fresh will produce the same flavor. Some herbs retain more flavor than others when dried. Basil, chives, parsley, chervil, and coriander leaves all lose some flavor components when dried, while rosemary, sage, and oregano stay much the same, just more concentrated.

## Using Herbs

Many fresh herbs should only be added near the end of cooking, otherwise their flavors are lost. Herbs such as cilantro, parsley, chervil, dill, and basil should all be added in the last few minutes of cooking or should be sprinkled over a dish just before serving. Dried herbs and some of the more strongly flavored fresh herbs like

rosemary, sage, and bay can be cooked for much longer. In parts of the Mediterranean and in some Asian countries, it is usual to serve a bowl of assorted fresh herbs or a salad made predominantly of herbs with the meal. This serves the twofold purpose of stimulating and revitalizing the palate and aiding digestion.

Green sauces are also popular in many cultures and can be used to add piquancy to an otherwise bland meal. These sauces are made by pounding fresh green herbs with a pestle in a mortar or a food processor. They can be as simple as a single abundant herb, a clove of garlic, and drizzle of olive oil all pounded together. They can be as complex as Italian pesto (pine nuts and basil), North African *chermoula* (coriander, mint, and parsley leaves), French sauce *verte* (parsley, tarragon, chervil, and chives leaves), and Yemeni *zbug* (coriander and parsley leaves), all of which also require a range of spices and other ingredients. These sauces are spread on bread, spooned into pasta or rice, added to soup, used as a marinade, spread over cooked meat, or used as a dip.

Much Southeast Asian cooking, especially in Vietnam and Thailand, demands fresh rather than dried herbs to obtain their distinctive flavors. Cilantro leaves and roots, lemongrass, garlic, ginger, turmeric, and chili are used fresh in traditional dishes from these countries. In contrast, Middle Eastern dishes use mainly dried and ground ginger and turmeric.

### Using Spices

Spices are an essential component of cuisines from all over the world. Spicy food is not necessarily hot. The heat in spicy food usually comes from pepper or chili. If these are not added to a spice mix, the dish will not have any heat. Nearly all spices are dried before use. They are best purchased whole and ground just before needed. If this is not possible, then one can buy ground individual spices or mixtures a little at a time and use them within twelve months. Many spices, whether used whole or ground, need to be lightly cooked before use. This enhances and in some cases changes the flavor of the spice. Whole spices can be spread over a tray and dry roasted for a few minutes in a hot oven. They can then be ground or left whole and added straight to a dish. Ground spices are best gently fried, without oil, in a frying pan for up to sixty seconds.

### Mixtures

Spice mixtures, which vary from country to country, are judicious combinations of spices that give a balance of flavors, often with surprising highlights. The various tastes of spices are usually categorized into five taste groups, sweet, pungent, tangy, hot, and amalgamating. Curry, for example, is a spice mixture that involves the selective use of pungent and aromatic spices. Some of these spices, like coriander, are added to almost every mixture; others, like star anise, are only rarely added to achieve a specific flavor.

Seed spices are an important component of many different breads, where they complement the carbohydrates and contain oils that aid digestion. Poppy and sesame seeds are used on bread rolls, nigella and black sesame seeds on Turkish breads, and caraway and dill seeds in and on many European breads. This use dates from antiquity, when different seed spices were used in cakes, biscuits, and breads to improve flavor and to help digestion.

### Traditional Uses

Hundreds of herbs and spices have been used in cultures all over the world for thousands of years. During this time countless traditions, myths, and rituals have evolved. The following gives just a taste of some of these.

In times past foul or nasty odors were often associated with evil, while sweet, fragrant scents indicated goodness and purity. Herbs and spices with strong or unpleasant scents were avoided, while the sweetly scented ones masked bad odors and protected against evil. Spices in particular were in demand to improve preservation and to disguise the flavor of rotten or foul-tasting food. The Romans used ginger to counteract rancidity. Ginger is also associated with the rites and passages of life. It is given to new mothers all over Asia to restore strength and vigor, while the Chinese see ginger as a warming (yang) and stimulating food, believing it calms and purifies. Closely related turmeric is used in Indian ceremonies to anoint brides, while in Thailand it is used to anoint novice monks before ordination.

Dill is an herb and a seed spice with a long history. Romans fed it to their gladiators to confer vitality, and in medieval times it was added to love potions. Some Americans know it as “meeting house seed” because at one time dill seeds were chewed to dull the pangs of hunger during long religious services. Parsley grew wild on remote Grecian hillsides, but the ancient Greeks did not usually eat it. They used it in funerals and as a symbol of death; to be “in need of parsley” meant that one was seriously ill. In early medieval England the slow and patchy germination of parsley was explained by the suggestion that, once sown, parsley went nine times to the devil and back before sprouting. Those with worries about hair loss were advised to sprinkle their heads with parsley seeds three times a year. Rosemary is another herb with connections to funerary rights. In France rosemary was customarily placed in the hands of the deceased before burial, and in England sprigs of rosemary were thrown into the open grave. Rosemary was also believed to aid memory. Greek students twined rosemary in their hair, believing the scent would stimulate memory. Tradition has it that where rosemary flourishes the women are in charge, while according to an Arabic proverb a person whose sage grows well will live forever.

The statuesque herb angelica has been used in pagan and Christian festivals for centuries. It is indigenous to cold northern Europe, and its name is derived from a legend in which an angel appears to a monk in a dream

## CLASSIC SPICE COMBINATIONS

### ***Panch Phora***

- 1 tsp. brown mustard
- 1 tsp. cumin
- 1 tsp. fennel
- 1 tsp. fenugreek
- 1 tsp. nigella

Whole seed mixture; fry or roast to release full flavor. Add to vegetables, seafood, breads, and pulses.

### ***Pickling Spices***

- 3 tsp. black pepper
- 3 tsp. yellow mustard seed
- 4 dried bird's eye chilis
- 3 tsp. allspice berries
- 3 tsp. dill seed
- 1 tsp. mace blades
- 1 crumbled cinnamon stick
- 2 crumbled bay leaves
- 2 tsp. cloves
- 4 tsp. ground ginger

Whole seed mixture, used to make pickles, chutneys, and spiced vinegar. Can be wrapped in muslin and removed before bottling.

### ***Garam Masala***

- 2 tsp. black peppercorns
- 1 cinnamon stick
- 1 tsp. cloves
- 2 tsp. cardamom seeds
- 2 tsp. cumin seeds

Grind the spices. Many different forms of this recipe exist, but they generally revolve around the same spices. Optional extras include bay leaves, coriander seeds, mace, and nutmeg. Use with fish, poultry, other meats, most vegetables, rice, pulses, and eggs.

### ***Mixed Spices***

- 1 cinnamon stick
- 1 tsp. allspice berries
- 1 tsp. whole cloves
- 2 tsp. grated nutmeg
- 2 tsp. ground ginger

Grind the whole spices. A traditional English mixture. Use in desserts, pies, cakes, and biscuits.

### ***Basic Curry***

- 10 tsp. coriander seed
- 5 tsp. cumin seed
- 1 tsp. brown mustard seed
- 5 whole bird's-eye chili
- 1 tsp. fenugreek seed
- 1 tsp. whole peppercorns
- 2 tsp. ground turmeric

Roast the whole spices, grind and mix all the spices together. Hundreds of different curries exist with varying combinations of the above spices. Other spices that can be used in curry mixes are fennel, cinnamon, cloves, cardamom, ginger, and curry leaves.

### ***Mexican Chili Powder***

- 5 tsp. chili powder
- 3 tsp. ground cumin seed
- 2 tsp. sweet paprika

Use to flavor chili con carne and other bean and minced beef recipes.

### ***Quatre Épices***

- 5 tsp. ground black pepper
- 2 tsp. ground cloves
- 2 tsp. ground ginger
- 2 tsp. ground nutmeg

A French spice mixture. Use in preserved meats like salami, with game meats, and with slow-cooked beef and chicken dishes.

### ***Chinese Five-Spice Powder***

- 1 tsp. black peppercorns
- 1 tsp. ground cassia
- 1 tsp. cloves
- 3 tsp. fennel seed
- 5 whole star anise

Grind the whole spices. Use with stir-fried vegetables and as a marinade for seafood, chicken, pork, and duck.

and tells him this plant can cure the plague. It was also believed that angelica protected a person carrying it against witches and their spells. Other sweet herbs such as lavender and rosemary sweetened washing water to scent clothes and, strewed around rooms, repelled insects and masked unpleasant smells.

## **Herbs and Spices in the Twenty-first Century**

Modern medicine led to a decrease in the use of herbal medicines in Western countries in the twentieth century. Nevertheless herbal remedies remain widely used in many poorer parts of the world, and herbal remedies have begun to regain popularity in the West. Many old uses

TABLE 2

## 20 common culinary spices

Name*	Description	Place of origin, climate	Part used	Quality and taste	Uses
Allspice <i>Pimenta dioica</i> Myrtaceae	Perennial, tall evergreen tree	Tropical, America and West Indies whole and ground	Dried and cured unripe berries	Pungent, clovelike	Sweets and cakes, pickles, preserved meats, curries
Caraway <i>Carum carvi</i> Apiaceae	Biennial, medium clump	Temperate, Europe and West Asia	Dried seeds, fresh leaves and roots mixes	Pungent, earthy with anise and orange	Breads, cheeses, pork, sausages, apples, cabbage, pastes, spice
Cardamom <i>Elettaria cardamomum</i> Zingiberaceae	Perennial, medium clump	Tropical, India	Dried pods and seeds, fresh leaves	Pungent, warm, camphorous	Fruits, cakes, biscuits, custards, curries, rice
Cassia <i>Cinnamomum aromaticum</i> Lauraceae	Perennial, tall evergreen tree	Tropical, Burma	Dried bark, whole and ground	Sweet, strong, slightly bitter	Pastries, cakes, biscuits, curries, spice blends
Chili <i>Capsicum</i> species Solanaceae	Short-lived perennial, perennial, small bushes to small trees	Tropical, America	Fresh and dried fruits and seeds	Hot, fruity	Spice blends, curries, pastes, sauces, sambals, pickles, dips
Cinnamon <i>Cinnamomum zeylanicum</i> Lauraceae	Perennial, medium evergreen tree	Tropical, Southern India and Sri Lanka	Dried bark, whole and ground	Sweet, mild, warm, woody	Stewed fruits, rice, curries, spice blends, sweet dishes, cakes, breads
Cloves <i>Syzygium aromaticum</i> Myrtaceae	Perennial, medium evergreen tree	Tropical, Moluccas	Dried flower buds	Pungent, camphorous, spicy, slightly peppery	Curries, spice blends, spiced wines, stewed fruits, custards, pickles, meats
Coriander <i>Coriandrum sativum</i> Apiaceae	Annual, small shrub	Temperate, Europe	Dried seeds, whole and ground	Amalgamating, citrus and sage	Cakes, pies, biscuits, fruits, curries, spice blends, pickles, sauces
Cumin <i>Cuminum cyminum</i> Apiaceae	Annual, small shrub	Temperate, Mediterranean	Dried seeds, whole and ground	Pungent, earthy sweet flavor	Curries, spice blends, rice, fish, lamb, breads, pickles, vegetables
Fennel <i>Foeniculum vulgare</i> Apiaceae	Herbaceous perennial, tall shrub	Temperate, Mediterranean	Dried seeds, whole and ground	Amalgamating, sweet anise	Salads, soups, spice blends, pastas, breads, sausages
Fenugreek <i>Trigonella foenum-graecum</i> Fabaceae	Annual, small, slender and Asia	Temperate, Southern Europe	Dried seeds, whole or dried leaves from seeds	Pungent, spicy and bitter	Vegetable and fish curries, spice blends, sprouts grown
Ginger <i>Zingiber officinale</i> Zingiberaceae	Perennial, spreading clump	Tropical, Asia	Fresh and dried, whole and ground roots	Pungent, spicy, sweet, warm to hot	Biscuits, cakes, fish, meats, vegetables, curries
Juniper <i>Juniperus communis</i> Cupressaceae	Perennial, shrubs to medium trees	Temperate, Europe and Asia	Dried berries	Pungent, savory, spicy, pine	Game meats, duck, pork, chicken, soups, stews
Nigella <i>Nigella sativa</i> Ranunculaceae	Annual, medium, erect	Temperate, Southwest Asia	Seeds	Pungent, black, bitter, slightly metallic tasting	Breads, spice blends, potatoes, curries
Nutmeg and Mace <i>Myristica fragrans</i> Myristicaceae	Perennial, evergreen medium tree	Tropical, Indonesia	Nutmeg-seeds, Mace-placental seed coverings, dried, whole or ground	Nutmeg-sweet, warm, aromatic Mace-pungent, spicy, sweet	Nutmeg-root vegetables, custards, cakes, biscuits Mace-seafood, meat sauces
Pepper <i>Piper nigrum</i> Piperaceae	Perennial, climber	Tropical, Southern India and Sri Lanka	Dried or pickled fruits	Hot, pungent, fragrant	Most savory foods
Saffron <i>Crocus sativus</i> Iridaceae	Perennial, small, bulbous	Temperate, probably Greece	Dried stigmas woody, fragrant	Pungent, earthy,	Rice, seafood, chicken, cakes
Star anise <i>Illicium verum</i> Iliaceae	Perennial, evergreen, small tree	Warm temperate to tropical, China and Vietnam	Dried fruits woody, aniseed	Pungent, spicy,	Vegetables, fruits, strong seafood, cured meats, sweet dishes
Turmeric <i>Curcuma longa</i> Zingiberaceae	Perennial, leafy clump	Tropical, India	Fresh and dried, whole and ground roots	Amalgamating, spicy, bitter	Spice blends, curries, fish, stir-fries, rice
Vanilla <i>Vanilla planifolia</i> Orchidaceae	Perennial, climbing orchid	Tropical, Florida, West Indies, Central and South America	Cured seed capsules	Sweet, fragrant	Desserts, cakes, biscuits, ice creams, sugar, chicken

\*Mustard is not included here as it is discussed in the text.

of herbs have been confirmed by scientists, while new uses are being found. For example, Taxol is extracted from yew trees to treat some cancers.

**HERDING.** Domestication of animals for food began about 10,000 years ago in the Near East, in the western part of the Fertile Crescent. This coincided with a period of climatic warming following the last retreat of the Pleistocene glaciation in Europe and Asia. Livestock provided a more regular supply of food that tended to mitigate, but not entirely eliminate, the seasonal patterns of resource availability that faced the hunter and gatherer. The Neolithic pattern of keeping animals for food followed shortly after the earliest domestication of plants in the same area of the Near East. Since that time other grazing and browsing animals were domesticated and their origins have been found at different sites around the globe. Table 1 lists major domestic species with earliest dates and places of domestication. All of these species can provide food in the form of meat, organs, marrow, blood, milk, or fat, although some function as draught, pack, or riding animals, and provide wool, hides, skins, hooves, and dung. When the earliest animals were domesticated, they were reserved for slaughter and their meat was used for food. Today, the livestock species listed in Table 1 constitute more than 3,000 breeds or domestic subspecies and provide a variety of foods and materials.

About 6,000 to 7,000 years ago, domestic animals began to be used for milking, wool production, and other

purposes in addition to meat in what Andrew Sherratt (1981) has called the "secondary products revolution." Milk production or dairying may have been practiced more than 7,000 years ago in the Near East since there is evidence for milking cattle and ovicaprids (sheep/goats) in Neolithic Europe that dates back to 6,000 years ago. A significant problem in the cultural development of dairying was the biological evolution of tolerance to milk sugar—lactose—through production of the digestive enzyme—lactase—beyond infancy by children and adults. Almost certainly the ability to utilize lactose by breaking down this disaccharide sugar into its digestible monosaccharides occurred by natural selection. The picture of adult lactose tolerance is a complex one of relationships among genetics, digestive physiology, and digestive enzyme adaptation. However, this is one of the best examples that we have of culture change (pastoralism to dairying) actually producing biological change (in genetics of populations) through natural selection.

Animal domestication and herding spread from centers in Eurasia to Europe, South and East Asia, and Africa. The pig was dispersed from Southeast Asia to New Guinea by least 3,000 years ago, and then later to the Pacific Islands. Much later, following Columbus's discovery, European domesticated animals were transported to the New World. In the indigenous New World, the Andean llama and alpaca were the only animals herded throughout North and South America.

Traditions of agro-pastoralism arose in moist areas or areas capable of irrigation: in marginal, semiarid, or arid lands, transhumant (seasonal migrations) and nomadic herding predominated. David Harris (1996) noted

**TABLE 1**

Earliest Domestication of Major Livestock Species				
Dates are in approximate years before the present				
Common Name	Species	Date	Place	Reference
Goats	<i>Capra</i> sp.	10,000	Near East (SW Asia)	1
Sheep	<i>Ovis</i> sp.	9,000	Near East	1
Pigs	<i>Sus</i> sp.	9,000	Near East, China	2
Cattle	<i>Bos</i> sp.	8,000	Near East, India	3
Horses	<i>Equus caballus</i>	6,000	Eurasian steppes	4
Water Buffalo	<i>Babalus babalis</i>	6,000	China	5
Camelids	<i>Llama</i> sp.	6,000	Central Andes	6
Donkeys	<i>Equus asinus</i>	5,000	NE Africa	4
Camels	<i>Camelus</i> sp.	5,000	Arabia (dromedary) Central Asia (bactrian)	7
Yak	<i>Bos grunniens</i>	>2,000	Tibetan Plateau	8
Reindeer	<i>Rangifer tarandus</i>	<2,000	Northern Eurasia	9

that the early Near East Neolithic (about 8,000 years ago) a “package” of foods that included cereals, pulses, goats, and sheep was particularly effective in providing a diet that contributed to population growth and expansion, and the spread of new subsistence practices.

Today, non-Western herding practices range from nomadic pastoralism in Africa, the Near East, and Asia to agro-pastoralism in the Mediterranean, Near East, Africa, and Asia. Diets are highly variable: some populations consume large amounts of animal products, whereas others trade animal products for cereals and sugar, and still others use animal products only to supplement a largely vegetarian diet. Since the earliest period of domestication, livestock have always contributed foods that are high in energy, balanced in nutrients, and both high and balanced in amino acids and the quality of protein. The cultural selection for a balanced diet became crucial to human health when the predominance of cereal and root crops in intensive agriculture contributed to dramatic population increases.

Several examples of pastoral diets can be drawn from Africa. There is considerable variation in food intake, where animal products constituted between 80 percent (Turkana) and 21 percent (Fulani and Baggara) of dietary intakes as a proportion of caloric intake. Moreover, in all these dairying populations milk is said to be a staple food. Other sources of human dietary variation are: (1) animal productivity, (2) seasonal changes, (3) the mix of animal species, breeds, and herd composition, (4) the patterns of animal use, and (5) trade practices. Animal productivity depends on the breeds of livestock, the forage productivity of the environment, and the patterns of herd management—such as ranching, sedentary, transhumant, or nomadic (Little et al. 1999). Well-fed stock will be larger and have more muscle mass and greater body fat deposits. Seasonal changes in semiarid ecosystems lead to loss of body fat and muscle mass in livestock, reduced milk pro-

duction in lactating females, and lower fat content of milk (Galvin and Little 1999). Different livestock species, breeds, and age/sex groups show variable food productivity; for example, dairy herds will have high proportions of females and high reproductive rates (population increase). Patterns of livestock use vary from largely food production (meat, milk, blood), to use of animals for traction, packing, or riding. In the case of Andean camelids, llamas are principally pack animals, while alpacas provide wool and meat. Trade of animal products for cultivated foods can substantially enrich diets. The concept of “verticality” in highland pastoral peoples entails exchanging of animal products for cultivated food from lowland populations. This is practiced by Indian Bakkarwal sheep and goat herders and by Peruvian Quechua llama and alpaca herders. Pastoralists depending principally on livestock products for food often will have very high protein intakes but low energy (calorie) intakes. Conversely, pastoralists who trade some of their animal products for cereal foods are likely to have adequate protein and higher energy intakes.

Herding of livestock is practiced today on all continents from tropical grasslands to Arctic tundra. More than 75 percent of world meat production in grassland-based ecosystems is from North America, South Amer-

## PRIONS AND MAD COW DISEASE

Prion diseases are produced by infectious agents that are proteins. These prion proteins resist inactivation by normal procedures because they do not have a normal nucleic acid genetic makeup. Prion diseases are often referred to as transmissible spongiform encephalopathies (TSE) because of the damage caused to the brain. The two livestock prion diseases that are known today are scrapie in sheep and bovine spongiform encephalopathy (mad cow disease) in cattle. Mad cow disease is transmissible to humans, and another human prion disease, kuru, was probably originally transmitted to humans through a modified form of scrapie via another prion disease called Creutzfeldt-Jacob disease. Mad cow disease is an example of a domestic zoonosis, that is, a disease that is transmitted from a domestic animal to humans. Two other domestic zoonoses that can be transmitted from livestock to humans are brucellosis or ungulent fever (present in goats, sheep, cattle, and pigs) and anthrax (present largely in cattle).

## DEFORESTATION AND LIVESTOCK GRAZING

Deforestation dates back in antiquity to the first rise of cities in the Near East about 5,000 years ago. Yet 2,000 years ago, in Roman times, 90 percent of Europe was still forested. Today, there are many causes of deforestation—living space for an increasing human population, agriculture, charcoal production, use of wood for fuel, commercial logging, and others. However, deforestation for herding of livestock, especially cattle, is one of the least productive uses for land. Increasing demands for beef and increasing numbers of fast-food chains internationally have contributed to the growth of cattle ranches in North and South America. It is estimated that more than 10 million hectares (24.7 million acres) of tropical forest are lost each year, and of these losses, about 10 percent or one million hectares are lost to grazing lands.

ica, Western Europe, Japan, Australia, and New Zealand. Residents of these major Western livestock producing nations (especially the United States, Argentina, and Australia) consume substantial amounts of animal protein and fat calories. Such dietary practices, when combined with sedentary physical activities, have contributed to high rates of cardiovascular disease in many of these Western nations. Another liability resulting from the close contact of humans and livestock are “zoonoses,” that is, diseases that originate in animal populations but are transmitted to humans. Examples are bacterial cattle diseases such as anthrax and brucellosis that are widespread around the world. Scrapie in sheep and mad cow disease are neurological degenerative diseases produced by pathogens called prions. When contracted by humans, they are almost always fatal.

Livestock productivity as food is low when compared to agricultural productivity, and requires either vast grazing lands or substantial importation and use of feed (Jordan 1993). Increasing demand for animal protein has certainly contributed to deforestation through cutting and burning of forests to maintain grasslands. And livestock manure is one of the major pollutants of bodies of water in the United States (Cincotta and Engelman, 2000). An estimate of the global livestock body mass in 1950 was about 340 million metric tons ( $3.4 \times 10^{11}$  kg). This biomass of livestock nearly doubled to an estimated 600 million metric tons ( $6.0 \times 10^{11}$  kg) in the year 2000 (Cincotta and Engelman, 2000). In contrast, non-Western livestock production in marginal lands that are unsuitable for agriculture (transhumant or nomadic herding) is an efficient system of animal food production that

is not environmentally degrading. However, this system of keeping herds represents an exceedingly small proportion of worldwide livestock productivity.

**HERODOTUS.** Known as the "Father of History," Herodotus (c. 484–424 B.C.E.) was born on the southwest coast of Asia Minor in Halicarnassus, which was at that time a Greek-speaking city ruled by Artemisia, queen of Caria, under the overlordship of the Persian Empire. Herodotus traveled widely in that empire and in Greece. Eventually, exiled from Halicarnassus, and having spent some years in Athens (where he gave regular readings of his work), he joined the new colony of Thurii in southern Italy, where he died.

Herodotus is the author of the earliest surviving work of history and one of the masterpieces of Greek literature. It is owing to him that the word "history" came to mean what it does: he introduces his book as "the inquiries (*historiai*) of Herodotus of Halicarnassus." The usual title in English translations is *The Histories*. His purpose was to explore the interaction, peaceful and warlike, between Europe (particularly Greece) and Asia (particularly the Persian Empire). Some of his best stories are of kings, but he takes just as much interest in the adventures of differently privileged people—physicians, athletes, merchants, priests, and cooks.

Book 2 of Herodotus's *Histories* focuses on Egypt (then subject to Persia) and North Africa. Books 1 and 3 include much information on Babylonia, Lydia, and other Persian provinces. Book 4 includes a survey of the peoples of Scythia (the Russian steppes).

One of the means by which Herodotus characterizes peoples is through their food behavior. His descriptions of the Egyptians, Persians, and other highly civilized peoples among whom he had lived are far more nuanced than those of "barbarian" peoples, most of whom he knew only by hearsay. The underlying message to his audience is different in the two cases. He was rightly impressed by the long history of civilization in Egypt and Babylonia and by the efficiency of the Persians: he seems to encourage the reflection that the lifestyle of these peoples is logical in its own terms, sometimes more logical than that of the Greeks, and may have been instrumental in their successes. Barbarian tribes, by contrast, are shown as making stranger and stranger food choices as they recede farther and farther towards the edge of the world, from agriculturalists to pastoral nomads to cannibals.

A structural anthropologist before the term was invented, Herodotus is not one to waste a promising structure. He asserts, and it is likely enough, that if the Persians took a decision while drunk, they made a rule to reconsider it when sober. Few authors between

Herodotus and Lévi-Strauss would have dared to add, as Herodotus does, that if the Persians took a decision while sober, they made a rule to reconsider it when they were drunk (*Histories*, book 1, section 133).

Herodotus is preeminent as a historian of the conflict of cultures. Throughout his work, food behavior is often the focus for sensitive and striking portrayals of culture clash. When Persian ambassadors visited the king of Macedonia, their stupidity in demanding the company of women at dinner, in conflict with local custom, was justly rewarded: the "women" who entered the dining hall were young men in disguise, armed with daggers, and the ambassadors were never heard of again (*Histories*, book 5, sections 18–20).

**HIGH-TECHNOLOGY FARMING.** During the twentieth century, farming changed more than at any time since it began. Crop and animal production in the United States went from a labor intensive to a capital-intensive operation. What caused these changes?

#### Crop Production

The revolutions in crop production started with the mechanical revolution that began with the plow, the planter, and the reaper, and the shift from horsepower to tractor power. The mechanical revolution started after the turn of the twentieth century with the replacement of the horse with modern tractors, combines, and cotton pickers. Since that time, machinery design has kept pace with the increased tractor power.

The second revolution in crop production began with the introduction of hybrid corn in the 1930s. Since then, average U.S. corn yields have increased from 25 bushels in 1930 to more than 140 bushels per acre today. Corn hybrids, along with other practices, greatly enhanced growing conditions so the genetic potential of the hybrid is expressed during most years. The plant breeding revolution has had similar impact on yield of other crops like rice, wheat, and soybean.

The third revolution in crop production came with the increased availability of fertilizers, particularly nitrogen fertilizer. The fertility revolution gained momentum

Hydroponic farming is demonstrated with cultures of lettuce at Disney's Epcot Center, Orlando, Florida. © JOSEPH SOHM; CHROMOSOHM, INC./CORBIS.

when munitions plants built during World War II were converted into factories for making nitrogen fertilizer. The ready availability of nitrogen fertilizer, along with better understanding of fertility through soil testing, improved fertilizer application and crop growth. Other nutrients like limestone, phosphorus, and potassium helped achieve the genetic potential of the crop. Fertilizer applications are still improving through variable rate applications as part of precision agriculture. Virtually every American farmer uses fertilizer to increase crop yields.

The fourth revolution is in the use of herbicides, insecticides, and fungicides to control weeds, insects and diseases that reduce crop growth. This revolution began in the 1950s. Modern weed control practices enable farmers to plant crops much earlier. Now corn and other crops grow during more favorable moisture and temperature conditions without competition from weeds for light, water, and nutrients.

The fifth revolution in crop production is the biotechnology revolution. It did not influence crop production until about 1995. Present benefits include better quality seed such as canola, insect resistant seed such as bollworm resistant cotton and corn borer resistant corn, seed with herbicide resistance such as soybeans, cotton, and corn. Many other changes are imminent. Use of seeds with herbicide, insect and disease resistance impact favorably on the environment because they replace less environmentally friendly chemicals. The revolution in

biotechnology promises to increase quantity and quality of the foods we eat.

The sixth revolution in crop production is the new availability of computers, software, and satellites. This technology enables what is often referred to as precision agriculture (PA). Precision agriculture technology enables advances from a data-poor to a data-rich environment. Previously, yields were measured by fields; now it is possible to measure yield continuously. The Internet affects farmers' business practices just as it does other types of business.

### **Livestock Production**

The farm livestock sector has changed dramatically in the past fifty years. Farms have gone from mixed crop and livestock operations to specialized livestock enterprises. Economic factors—the comparative cost of land, labor, capital, and environmental regulations—have brought about these changes. The cost of labor and land per animal fell dramatically while capital investment and environmental costs increased. Farms with small herds and flocks yielded to large specialized farms with large animal concentrations.

Before 1950, farms had many different crops, including hay and pasture, as well as various types of animals: cattle, hogs, and chickens. In the twenty-first century, there are large specialized farms: dairies, beef feedlots, hog operations, and chicken and turkey houses.

Such operations use small land areas or are housed entirely inside buildings. Many animal units can be managed with small amounts of labor. The result is animal farms where all the best health controls are available and applied to keep herds and flocks healthy.

Computer technology has increased the amount and way data is collected. Dairies know the daily and annual milk output for every cow in the herd; hog farmers know the weight gain and feed conversion efficiency of every sire used in their breeding operation; cattle feedlot managers know the weight gain and the carcass quality of every animal; and poultry producers know the feed-to-meat ratio of their broilers and the egg production of each laying hen.

The ease of obtaining data by computer and the ready availability of well designed equipment and buildings has decreased labor and enabled increases in size of animal operations. Increases in the economic efficiency of producing meat and eggs have reduced the cost of products at the grocery store. While many small animal operations exist, most production is from larger operations. Biotechnology's promise for animal agriculture is comparable for crop production and will lead to many new products.

Animals such as cattle, sheep, and goats still graze land too rolling, too dry, or otherwise not suited for crop production. Such cow-calf and sheep operations harvest the biomass that would otherwise be uneconomical to harvest and supply feedlots with animals. Land well suited for crop production—flat, with adequate rainfall or available irrigation—has reduced animal grazing during the past twenty to fifty years.

### Summary

Crop and animal agriculture has changed more in the past century than it has since farming began many millennia ago. Modern-day crop production practices, often called precision agriculture (PA), benefited from all earlier revolutions in crop production. Precision agriculture technology developed because of ubiquitous and inexpensive computational power, software (GIS), and satellite location systems (GPS). Precision agriculture equipment enables variable-rate fertilizer, herbicide, plant population, and yield assessment. Wide adoption of PA equipment will occur as it becomes economical. Technology has moved crop production from a high labor and low capital intensive to a low labor and high capital intensive industry. Typical Midwest Corn Belt farms have gone from less than 160 acres to more than 500 acres. The labor necessary to produce a bushel of corn decreased from more than thirty minutes in 1930 to a fraction of a minute in 2002. Availability of high powered well designed equipment; well-adapted hybrids and varieties; precise weed, insect, and disease control; improved plant and animal genetics; and improved animal health have all contributed to the revolution in plant production we have discussed. Biotechnology and computer

revolutions enable us to manage large operations and design crops and animals that will be more nutritious in the future. Consumers are the major beneficiary of these developments since food purchases now requires less than 10 percent of average income.

**HINDU FESTIVALS.** India is a land of bewildering diversity, a unique and colorful mosaic of people of various faiths. There is a festival for every reason and for every season. Many festivals celebrate various harvests, commemorate great historical figures and events, or express devotion to the deities. Every celebration centers around the rituals of prayer and seeking of blessings, and involves the decoration of homes, wearing of new clothes, music, dancing, and feasting. Festivals are an expression of the spirit of celebration. They are observed with enthusiasm and gaiety and are occasions when the greater family and friends come together. They also present women with an opportunity to socialize. Many of these festivals are associated with special foods.

Among the most important Hindu festivals are Makar Sankranti, Shivratri, Holi, Onam, Ganesh Chaturthi, Dussehra, and Diwali. They are celebrated throughout the country in various forms.

### Makar Sankranti

Also referred to as Lohri in the North and as Pongal in parts of the South, Makar Sankranti is a celebration of the "ascent" of the sun to the North. The festival marks the coldest day of the winter (14 January), after which the biting cold begins to taper off. In the North, the festival is marked by the lighting of bonfires, into which

sweets, rice, and popcorn are thrown as offerings. In the South, prayers are offered to the sun god, because without the sun, there would be no harvest. During the festival, the most commonly eaten foods are sesame seeds and jaggery sweets, rice cooked with milk, jaggery (called *pongol*), and sugar drops. Jaggery is a dark crude sugar made from palms.

### Shivratri

Shivratri literally means the night of Shiva. It is celebrated in February and March. Devotees of Shiva abstain from eating food throughout the day and only break their fast the following morning after a night of worship. The offerings of food to the deity comprise “cooling” foods, because Shiva was said to be hot-tempered. These include milk, water, honey, and the leaves of the wood apple tree (*aegle marmelos*), which are said to be cooling. Another food popular at this festival is *thandai*, a drink made with milk, almonds, and hemp seed. Hemp seed is said to have been dear to Shiva and is thus imbibed as part of the festivities.

### Holi

Celebrated essentially in northern India, this boisterous festival heralds the onset of spring (in mid-March). It is a festival of color, and people smear each other with colored powder and spray each other with colored water. Singing and dancing add to the gaiety of the occasion. It is variously associated with Krishna (as is evident in the particularly extensive celebrations at Vrindavan and Mathura, the two places associated with Krishna) and Shiva. Legend has it that the celebration of Holi is actually a recreation of the marriage procession of Shiva. The delicacies eaten during this festival include *malpua* (fresh bread soaked in a sugar syrup), *puranpoli* (unleavened wheat bread stuffed with lentils and jaggery and baked on a griddle), and *gujiyas* (flour patties stuffed with milk solids, sugar, almonds, and raisins and then deep-fried).

### Onam

Onam, the harvest festival, is traditionally celebrated in Kerala (in August–September). The harvest has been reaped and the granaries are full; therefore it is time to rejoice.

### Ganesh Chaturthi

Celebrated essentially in Maharashtra, this festival celebrates the birthday of Ganesha, the elephant-headed god who is the son of Shiva and Parvati. Ganesha is the remover of all obstacles and difficulties; he is the one who will grant success in all human endeavors. Therefore, no new venture is started without first praying to Ganesha. His image is installed in individual homes for a period of hours or days leading up to the festival, at which point those same images are displayed in a procession with much singing and dancing, and then immersed in running water. Ganesha's favorite food *modak* (a wheat flour pastry stuffed with coconut and jaggery and baked on a

griddle) is offered to the deity and served throughout the festival's duration.

### Dussehra

Celebrated in October, Dussehra commemorates the victory of good over evil, and culminates in the burning in effigy of Ravana and the triumph of Rama. It is celebrated in various ways throughout the country, often with much music and dancing, and lasts for ten days. During this time, there are public performances of the Ramlila (the story of the Hindu epic, the Ramayana). On the day of Dussehra, new accounts are opened, and new ventures started.

### Diwali

Celebrated twenty-one days after Dussehra, this festival commemorates Rama's return to his hometown, Ayodhya, after having been in exile for fourteen years. While Dussehra celebrates Rama's victory over Ravana, Diwali celebrates his return. Thousands of oil lamps are lit to welcome him home, making it a night of enchantment. Homes are decorated, and sweets are exchanged between family and friends. Fireworks and festivities are part of the celebrations. On this day, the goddess of wealth, Lakshmi, is worshipped.

**HINDUISM.** Hinduism is a religion, a philosophy, and a way of life. It guides people along paths that will ultimately lead to the individual soul (Atman) becoming one with the Universal Consciousness.

The religion recognizes that everyone is different and has a unique intellectual and spiritual outlook. Therefore, it allows people to develop and grow at their own pace by making different spiritual paths available to them. It allows various schools of thought under its broad principles. It also allows for freedom of worship so that individuals may be guided by their own spiritual experiences. This freedom of worship permits individuals to worship in any place, be it a church, mosque, or *guru-dwara*. The tolerance shown by this religion to other faiths is unmatched. Hinduism has never been imposed on anyone, whether on a subjugated people through wars, or by offering spiritual or economic benefits to the poor.

The strength of Hinduism lies in its adaptability to the infinite diversity of human nature. It has a highly spiritual and abstract side suited to the philosopher, a practical and concrete side suited to the worldly individual, an aesthetic and ceremonial side suited to the person of poetic feeling and imagination, and a quiescent and contemplative side suited to the lover of peace and seclusion.

Hinduism is also unique in that it has adapted itself to include numerous ideals and precepts of other religions, such as those of Jainism and Buddhism. For instance, among many communities, offerings of rice and ghee (or clarified butter) took the place of animal sacrifice—a compromise with Vedic ritualism. Many of the early Aryans had been meat eaters, but under the influence of Buddhist and Jain ideas, numerous groups of Brahmins and non-Brahmins became vegetarian.

Another feature unique to Hinduism is its belief that liberation or deliverance (*moksha*) can be achieved in this life itself: one does not have to wait for a heaven after death.

### Hindu Beliefs as Reflected in Food

**Rebirth or reincarnation.** The Hindus believe that one must go through several births and rebirths before attaining liberation. The hardships of the current world are a result of the actions of a previous life that have to be atoned for in the present life.

**Karma.** The law of karma (or action) also supports the above theory. It suggests that every action has a similar

or related reaction. Although it is not possible to change one's past life, it is possible for one to shape the future and to pave the way for a better life in rebirth through the actions of the present.

**Dharma.** Dharma refers to duties that have to be performed at different stages of one's life. These must be completed without a thought of possible rewards or benefits and should also be accomplished to the best of one's ability. They are responsible for the prevailing social order in the world. There are four stages of Dharma:

- Student or Brahmachari—This first phase involves living and studying with a guru.
- Householder or Grihastha—This next phase starts with marriage.
- Retirees or Vanaprastha—The third phase occurs when the duties of child rearing and work are over.
- Sanyasi—This is the final phase when all worldly desires are renounced and the individual spends all of his or her time in meditation.

### Hindu Scriptures

Hinduism is based on the Eternal Truth as it has been explicitly defined in the scriptures:

1. The Srutis come from the Vedas, of divine origin and unchangeable. They encapsulate the greatest truths.
2. The Smritis, referred to as the Dharma Shashtras, are of human composition. They govern the daily conduct of people, including the actions of the individual, the community, and the nation, and may change over time.
3. The epics are those stories or fables in which the philosophy of the Vedas is told. The most important epics are the Ramayana and the Mahabharata.
4. The Puranas are the Hindu scriptures that convey the truths of the Vedas and the Dharma Shashtras in the form of tales. These stories form the basis of religious education for the common man.
5. The Agamas record the doctrine for the worship of different deities, including Shiva, Vishnu, and Shakti.
6. The Darshanas encompass the six schools of Hindu philosophy; they guide scholars.

### Hindu Gods and Goddesses

Hinduism has many gods and goddesses, some of whom were worshipped by early peoples who later came into contact with this faith. The aim of Hinduism is not the worship of any one of these deities, but rather the means with which the individual soul or Atman will become one with the Brahman, or the Universal Soul. Among the most commonly worshipped gods are:

- Nirguna Brahman—The Universal Soul who transcends time and space and is formless.

Popular print of Ganesha, the Hindu god of wisdom and prudence. He is usually depicted as a man with an elephant's head. The print dates from circa 1930. ROUGHWOOD COLLECTION.

chosen by very few, usually scholars. Knowledge of the Vedas, Upanishads, and Bhagavad Gita is essential.

**HIPPOCRATES.** Hippocrates (460–377 B.C.E.), a disciple of Democritus, was a Greek physician who is now considered the father of Western medicine. Born on the Greek island of Cos, he was associated with the cult of Asclepius, the Greek god of healing whose staff entwined with a serpent became the symbol of medicine. In the seventh century B.C.E., Asclepius, aided by his two daughters, Hygeia and Panacea, superseded Apollo as the greatest of the healing gods, and temples in his name were built to heal the sick. According to legend, the centaur Chiron taught Asclepius pharmaceutical knowledge about drug plants.

Hippocrates, considered the originator of a Greek school of healing, was the first to clearly expound the concept that diseases had natural rather than supernatural causes. Various works attributed to him and to his school are contained in the Hippocratic Collection, which includes The Hippocratic Oath, Aphorisms, and various medical works. He was an expert in diagnosis, predicting the course of disease. Based on the color and pallor of the ill person, disease was considered to be an imbalance of the four “humors”—blood, phlegm, yellow bile, and black bile—a concept that was to affect medicine for the next two thousand years. This concept persists in the following terms that describe distinctive temperaments: sanguine (warm and ardent), phlegmatic (sluggish, apathetic), and bilious (ill humored). Healing emphasis was placed on purges, attempts to purify the body from the illness produced by excesses or imbalance of humors. Hippocrates particularly noted the influence of food and diet on health, recommending moderation.

In the work *On Ancient Medicine*, Hippocrates notes differences in individual responses to food. He comments

- Saguna Brahman—The concept of Ichwara, the Great God, with a form upon which the individual mind may fixate during prayer and meditation.
- The Trinity—As personified by the three attributes of Ichwara, including their feminine dimensions: creation (Brahman), preservation (Vishnu), and destruction (Shiva).

#### Attaining Moksha

There are essentially three paths to attain oneness with the Universal Consciousness:

1. Bhakti yoga (the path of devotion)—The vast majority of people choose this path of single-minded devotion to a favorite god.
2. Karma yoga (the path of action)—Those who choose this path believe in the dictum “work is worship.” No job is too menial or too low for this devotee, as all work is a means of realizing God.
3. Jnana yoga (the path of knowledge)—This is perhaps the most difficult of the three paths and therefore

on the fact that some can eat cheese to satiety while others do not bear it well, a diagnosis of what we would now call lactose intolerance. The use of drugs was also an area of study: between two hundred and four hundred herbs were mentioned by the school of Hippocrates.

**HOLIDAYS.** Holidays are “holy days,” when people interrupt the profane, mundane round of production and celebrate with the preparation and eating of special foods and meals. The two basic forms of holidays are a festival (from Latin *festum* for ‘feast’), when people break their normal weekly, monthly, or annual routine to celebrate together, and a vacation (in the sense of leaving their homes and workplaces empty), when an often longer disruption may be accompanied by dislocation, as people change residences or travel.

#### Festivals

Traditionally, festivals have enjoyed an explicitly religious interpretation, so that the Sabbath of Jews, Christians, and Muslims is a God-ordained day of rest. Many holidays have been associated with seasonal change, and the New Year is celebrated in many calendars, notably the Chinese, with brilliant feasts. Other festivals have been national, ordered by governments to honor founding events and heroes, such as Bastille Day (14 July) in France. Further holidays might commemorate children, an emperor’s birthday, the achievements of war veterans or the working class. Australians take legislated days off for horse races.

Festival foods often feature in cookery books, such as the multivolume *Foods and the World* series of Time-Life (1968–1971). Conversely, festival foods are often described in surveys of holidays around the world, such as *Holidays and Festivals* (1999). Traditionally, women have worked together for several days on elaborate preparations, such as finely decorated confectionery and pastries, which have been keenly anticipated each year and have long remained poignant reminders of local, ethnic, and religious affiliations.

Eating and drinking might become especially abundant at harvest festivals and the breaking of a fast, as when Carnival concludes the Christian Lent and at the end of Ramadan, the ninth month of the Muslim year. Particular foods might be featured, such as the lamb and unleavened bread of the Jewish Passover. The Hindu festival of lights, Divali, celebrates the longest night of the year (which falls in October or November in the Western calendar) with gifts of sweets, which vary immensely across the subcontinent. The Scottish *haggis*, which is a boiled sheep’s stomach stuffed with mutton offal and oats, is a triumph of symbolic grandeur if not culinary, typical of midwinter and so featuring at *hogmanay* (New Year’s Eve) and again on Burns Night (25 January), which commemorates the birthday of poet Robert Burns, who praised the *haggis* as the “great chieftain o’ the puddin’-race.”

Thanksgiving (the last Thursday in November) is a national American feast on which families dine on turkey and traditional accompaniments. The warmer weather of Independence Day (4 July) encourages parades and more casual, outdoor eating, especially barbecued chicken and perhaps an apple pie or red, white, and blue cake. Particular foods tend not to be associated with newer holidays, and yet the community mindedness of Martin Luther King’s Day (the third Monday in January) might be reflected in sharing minority cuisines and decorating paper bags for food deliveries to the needy.

#### Vacations

Monarchs frequently took their court on an extended voyage through the countryside from palace to palace. Other leisured classes have long avoided either extreme of temperature by “summering” or “wintering” at an alternate house or resort. With the expansion of rail and road networks and the democratization of the annual break, more people took vacations. They could grow up knowing life on the farm from childhood holidays spent with cousins, could visit distant relatives when several national holidays coincide (such as Christmas–New Year’s and the Japanese “Golden Week”), and could experience the products of hotel, restaurant, and other kitchens, sometimes in foreign countries, where everything might be closed for an unexpected holiday of pageantry and feasting.

#### The Effect of Globalization on Holidays

Whether in premodern China, ancient Rome, medieval Europe, or modern industrial societies, the proportion of holidays has remained remarkably constant—approximately one day in three. However, with globalization, and more continuous production and consumption, fewer collective breaks are observed. The seasonal emphasis is giving way to consumer weekends, a few national days, plus individual annual leave. Religious feasts are losing out to sport and entertainment, gift-giving breaks such as Christmas are commercially exploited, and vacations are serviced by organized leisure and tourism industries.

The innocent “holiday mood,” which has been relished not just by the holidaymakers but novelists and screenwriters, is in danger of being lost. Holidays provide scenic locations, laid-back atmospheres, and breaks in everyday routines for the unexpected to happen. A gem of the French cinema, Jean Renoir’s *Une partie de campagne* (often translated as *A Day in the Country*, 1936/46), centers around a Parisian family picnic at a country inn, during which two men invite the mother and betrothed daughter to go boating. In *Le Rayon vert* (*The Green Ray* or *Summer*, 1986), director Eric Rohmer shifts his listless heroine to various French holiday destinations, and she memorably justifies her vegetarianism over an outdoor lunch. Hollywood has often taken teenagers on summer holidays for lessons in growing up, their chosen meal typically milkshakes and hamburgers.

The association between holidays and foods may be lessening, yet it persists in many ways, and understanding the genesis of holidays assists in continuing to reinvent them.

### Explaining Holidays

The Russian author Mikhail Bakhtin in *Rabelais and His World* (1968) analyzed the carnivalesque, the inversions when aristocrats and servants change places, when scatological humor temporarily undermines the dominant ideology, and when eating reappears as a “grotesque” reality. More conventionally, such boisterous breaks as Mardi Gras are often said to “release” pent-up energy that might otherwise be destructive.

Other social scientists have viewed holy days as “sacred” moments that give shape to otherwise “profane” time. Developing this approach from Émile Durkheim, anthropologist Edmund Leach asks in “Two Essays concerning the Symbolic Representation of Time” (1961) why people dress up in “false noses” or, more precisely, adopt three types of behavior: increased formality (such as an English Sunday), masquerade (New Year’s Eve revelry), and role reversal (Mardi Gras). He then argues that such activities generate and reinforce sacred time (so that “transgressive” and “sacred” accounts are not so different). Such holidays contribute to social cohesion, not only reinforcing a common interpretation of the world, but also facilitating a rhythmic pattern of activities and so the “ordering of time.”

Food is then usually regarded as “symbolic” of sacred time. Yet the inverse often makes better sense because holidays are grounded in cycles of food production. The interruption in “profane” routine by joy, revelry, or contemplation generates the holy. A harvest festival is an obvious case, when an intense burst of consumption follows a busy period of gathering and preserving, and when people are no doubt so profoundly thankful that they bring these crops before the gods.

Likewise, lamb might “represent” Easter, but while offering first fruits might come to “symbolize” spring,

before that, the rejoicing at their arrival generates the concept of spring. The word “Easter” comes from the old English *easter* or *eastre*, a festival of spring, and its lambs, eggs, and rabbits are more than mere “symbols” of spring; they are spring. The Jewish festival of Passover derives from the Hebrew’s nomadic origins, when the new growth would have supported extended gatherings, celebrated by sacrificing some of the newly increased flock. Since Jesus had been put to death around the time of Passover, Christians adopted the symbolism of Jesus as a sacrificial lamb.

The trappings of Christmas belong to the phalanx of “pagan” midwinter festivals; the merrymaking and exchange of presents join the ancient Roman festival of Saturnalia and other cheering anticipations of cornucopia. With no certain tradition as to the date of Jesus’ birth, Emperor Constantine chose the winter solstice, possibly to “compete” with the other festival, as often stated, but more likely to place Jesus’ birthday appropriately at the beginning of the year.

Not only the seasonal festivals but also the weekly are based on the food supply. In different cultures, weeks have comprised three, four, five, six, seven, ten, or other number of days. With few exceptions, these have been organized around the market cycle. A strict periodicity must be maintained for both the circuit of sellers and the attendance of buyers. The Christian world took the seven-day week from the Jews, who had adopted it from the Babylonians.

Marking out the market week and seasonal year, festivals dramatize the cycles of food production and consumption upon which our survival depends. The feasts become time-keeping devices, proto-calendars. For, in another inversion of a common assumption, holy days were not the products of formal calendars, but their antecedents. Festivals originally had ecological dates, because they related closely to winter scarcity, bud-burst, arrival of flocks of birds or schools of fish, the weakening of the monsoon, and other natural cues. With precise astronomical observations, central authorities then created rational calendars and so, eventually, more “exact” festivals.

### Upholding Holidays

Commercialism has boosted Christmas, Mother’s Day, Father’s Day, and others. Among ancient holidays that have gained new life, Valentine’s Day encourages couples to dine out, and Japanese women to give chocolates. The food and drink industries have introduced a range of festivals, not the least the return of weekend farmers’ markets, and annual food and wine fairs replete with tastings and grand banquets.

The mobility of global populations might have made many holidays anachronistic in that traditional meals are out of season; for example, Christmas turkey and plum pudding are absurd in the middle of the hottest days, as

happens in the Southern Hemisphere. Yet people adapt, and many Australians enjoy the heavy fare during their winter, on 25 June or 25 July (for some reason, seven months out seems to be preferred). People invent their own rituals to surround a global television event, such as the annual telecast of the Academy Awards.

The individualization of holidays encourages new approaches. The registration of precise dates of birth has helped make this an important anniversary; many people ask for their birthday off from work, and even attach an appropriately seasonal food or meal. Married couples, probably having conducted much of their courtship over dinner, having founded their new household at a wedding breakfast, and then having gone on a honeymoon, celebrate wedding anniversaries at a romantic dinner at a restaurant or weekend retreat. Perhaps they celebrate other milestones, such as the departure of children from the "nest." People take other rites of passage seriously, such as reaching adulthood at the age of eighteen or twenty-one.

Influential American and British cookery writers discovered the joys of traditional European cuisines on sojourns after World War II. Many others now make an annual gastronomic tour, steered by the "stars" in restaurant guidebooks. Food and wine-producing areas have become tourist attractions. Enthusiasts take cooking lessons in Tuscan villas.

More modestly, a holiday is a chance to catch up with household chores, for a city worker to spend time in the kitchen, or for everyone to go on a picnic. People shift to a beach or mountain house to get away from the clamor of newspapers, television, and junk mail, and go fishing or hunting. Stressed workers still need time to read, to chat over coffee, to walk along the beach, to linger over meals, to philosophize into the night. Even more fundamentally, human beings need to keep in touch with the seasons. Given the range of the world's climates, clinging to the best local products is a force for difference.

**HOME ECONOMICS.** From its beginnings, the profession of home economics, also called family and consumer sciences, closely paralleled the general development of education for women. Home economics developed out of political, economic, and technical conditions in the last half of the nineteenth century. Before then, formal training for women was virtually nonexistent. What did exist was the realization that obligations of the home extended beyond its walls. The discipline was begun by men and women, including Ellen H. Richards, Wilbur O. Atwater, Edward L. Youmans, and Isabel Bevier, who aimed to develop a profession that understood the obligations of and opportunities for women. They wanted to use scientific principles and processes to enhance management of households, and they wanted to make home and family effective parts of the world's social fabric.

Family and consumer sciences or home economics, as taught and practiced in the United States and abroad, has a broad and comprehensive focus. A plethora of names, including domestic science, living science, home science, home science education, human ecology, human sciences, practical life studies, household technology, science of living, family and household education, family and nutritional studies, and nutrition and consumer studies, also have been used to describe the discipline, whose purpose is to meet specific and general needs of individuals and families. Although the names were numerous, a single widely accepted definition was adopted at the 1902 Lake Placid Conference on Home Economics, one of ten such conferences held annually from 1899 to 1908 devoted to the study of laws, conditions, principles, and ideas concerned with a person's immediate physical environment, his or her nature as a social being, and the interrelationships therein.

#### Founding Home Economics

Publications, such as Catharine Beecher's *A Treatise on Domestic Economy* (1841), and legislation, including the Morrill Act (1862), probably provided the impetus for the Lake Placid conferences. The Morrill Act devoted federal lands to support the development of colleges of agriculture and mechanical arts. This helped shape the field of home economics because women subsequently were admitted to these land-grant colleges, as they were called,

and to some private institutions, such as Oberlin College in Ohio.

The first home economics class in an institution of higher learning was offered at Iowa State College in 1871 and was called “domestic economy.” Kansas Agricultural College began its domestic economy curriculum two years later, and Illinois Industrial University followed a year after that. These and the others that followed helped women apply theories in arts and sciences to everyday living. As they studied domestic economy along with some classical curricula and as theirs became an academic discipline, educational opportunities for women expanded.

Concurrently the interest in adult education courses expanded. Prior to the last quarter of the nineteenth century, women’s work was mostly needlecraft, sewing, and cooking; the work was done at home; and women received little formal educational training for these tasks. Some classes in cookery existed, such as those at the Boston Cooking School begun by Maria Parloa, and Mothers Clubs and Reading Circles developed. In time, all of these organizations had major impacts on communities. Mothers Clubs and Reading Circles became Parent Teacher Associations, and the Society of the Study of Child Nature became the Child Study Association.

Ellen Richards influenced the field of home economics and all of women’s work. Considered the founder of the profession of home economics, she became in 1873 the first woman to earn a bachelor of science degree at the Massachusetts Institute of Technology (after earning an A.B. from Vassar in 1870). She published *The Chemistry of Cooking and Cleaning* and a manual for housekeepers, both in 1881. Some years later she worked on an exhibit in Chicago for the World’s Columbian Exhibition (1890) based on her nutrition experiments. This exhibit was influential in establishing the first school lunch program in 1894.

Academic and adult education courses as well as increased immigration, industrialization, and urbanization added impetus for the development of this discipline, initiated at the first Lake Placid Conference on Home Economics in 1899. Three years later the conference founded a national organization, the American Association of Home Economics (AHEA), which actually began its work in 1909. The goals of AHEA were to improve living conditions in homes, institutional households, and communities. Conference participants selected subject matter that stressed family applications and developed academic requirements in cultural, technical, and vocational venues. These originally included the areas of food, clothing, shelter, and institutional management and shortly thereafter expanded to include child development, personal and family relationships, consumer education, home management, and housing.

Participants at the Lake Placid conferences designed the discipline’s educational requirements in natural and

social sciences and the arts and humanities for elementary and secondary schools and institutions of higher education. They also developed ways to access funding to implement these goals, including advocating passage of the Smith-Lever Act of 1914 and the Smith-Hughes Act of 1917. These two acts established, respectively, the Cooperative Extension Bureau and education in home economics at precollege and college levels. These efforts developed ties between institutions of higher education and teacher preparation.

World War I created demands for professionals trained in institutional management and dietetics, natural situations for home economists. After the war, additional demands arose in public health, community feeding, school lunch supervision, consumer protection, and related areas. These demands expanded the discipline’s activities well beyond cooking and sewing. During the depression of the 1930s, home economists were further called upon for advice in managing family needs. These newer roles required that institutions of higher education develop and emphasize research and divide their educational offerings into narrower specialties.

These circumstances, along with a 1930 AHEA report, changed training for professionals. The training kept physiological, psychological, economic, social, and political perspectives; increased emphasis on sociology, economics, and philosophy; and decreased required courses in education, science, and home economics. This shifted the emphasis from home-related skills to those needed in away-from-home situations. Additional changes during and after World War II expanded preparation and broadened professionals’ areas of service.

The AHEA suggested ways to strengthen family life, expanding offerings and reducing skills courses for the five largest areas of the profession, that is, home economics education; child development and family relations; textiles, clothing, and fashion merchandising; general home economics; and food, nutrition, and dietetics. Building on the basic disciplines, the AHEA promoted more research relating to nutrition, child development, consumer economics, and home management to increase the discipline’s impact on families, homes, consumers, legislation, and technology, and on all types of households and related institutions.

### Late Twentieth-Century Developments

No other discipline integrates so many applied and theoretical areas of education or reaches out as far as home economics. Many conferences, committees, and research efforts have kept the AHEA and its constituents current. In the 1960s efforts were expended toward accreditation of all undergraduate programs, achieved in 1967. The eleventh Lake Placid Conference met in 1973 to revitalize values and to develop future directions to broaden home and family life into an ecosystem conceptualization, emphasizing interdependence of people in rapidly changing environments. In the 1980s the organization

focused on certification of professionals, which began in 1986.

Reaching out to meet the demands on professionals, AHEA was instrumental in organizing a professional summit to build consensus among five related organizations, including the AHEA, the home economics division of the American Vocational Association, the Association of Administrators of Home Economics, the National Association of Extension Home Economists, and the National Council of Administrators of Home Economics. At a conference in Scottsdale, Arizona, in 1993 these organizations opted to change the discipline's name from home economics to family and consumer sciences (FCS), for which the memberships favorably voted the following year. In 1997 national standards for middle and high schools were developed and adopted for FCS education, focusing on content, process, and competencies.

Positioning itself for the twenty-first century, the profession developed additional ways to empower individuals and families to take charge of their lives, to maximize their potential, and to function independently and interdependently. To further these means of empowerment, FCS and related professionals work together to create opportunities and options for their diverse constituencies, and they have made strides to increase minority membership and leadership. In addition, they have set standards for integration and application of knowledge among all peoples and constituencies. FCS professionals, with the help of others who share the same goals, have moved women's work toward the center of higher education. They have impacted society and continue to work so all professionals can see efforts in the home and the community increased and gender marginalization reduced.

The national organization, renamed the American Association of Family and Consumer Sciences (AAFCS; renaming effective 1994), promotes improvements in individual and family life. Its efforts effect changes in areas such as food, nutrition, textiles, clothing, family relationships, child development, family resource management, design, housing, and consumer studies. Using its unique, integrated approach, it strengthens and empowers individuals, families, and communities, enhancing the quality of life. The profession strives for positive change in the multifaceted environments and ecosystems in which people live, work, and otherwise partake of life.

**HOMELESSNESS.** No nation is without its homeless. In the United States alone, between 280,000 and 600,000 men, women, and children are homeless each night, according to differing estimates. They are without permanent lodging because of poverty, lack of affordable housing, low wages, substance abuse, mental illness, or domestic violence. In many other countries, however, civil unrest, war, and famines bring about homelessness. At the beginning of the twenty-first century, there were more than eleven million homeless worldwide.

Paramount among the problems facing the homeless are poor nutrition and hunger. They can be life-threatening, especially among refugees. Protein-energy malnutrition is a major contributory cause of death among newly displaced refugees. International relief organizations and the United Nations set up refugee camps and make the distribution of nutritionally adequate food rations a high priority. The homeless in the United States often do not experience such extreme food deprivations. However, many are often chronically undernourished. Compared to other groups at risk for hunger, the homeless are at greatest risk, being ten times more likely to go without food for a day compared to the poor. Few are able to obtain three meals a day, and many go at least one day a month without any food. Scant research indicates that many have caloric intakes far below recommended levels and may have inadequate intakes of calcium, folacin, iron, magnesium, or zinc. Their low-calorie diets, which tend to be high in fat, cholesterol, and sodium and inadequate in essential nutrients, may further compromise the already poor health status of the homeless.

While many rely on homeless shelters, especially in winter months, a large number find refuge in cars, abandoned buildings, on grates, in parks, or, other outdoor places. Most have been without a fixed and regular nighttime residence for more than one year. Lacking a stable home environment and cooking and storage facilities exacerbates their inability to obtain an adequate, varied, and

healthy diet. While it is not uncommon to see a homeless person panhandling or scavenging for food through trash cans, most depend on soup kitchens and shelters for the major portion of their daily nourishment. Soup kitchens and shelters typically serve one meal a day on-site, although some shelters permit their residents to prepare and cook their own meals. Those who are substance abusers or have mental health problems are more likely to resort to obtaining food from trash cans or begging, compared to those without these health conditions.

Participation in the Food Stamp Program, the government's largest antihunger program, is unusually low among the homeless. While homeless advocates speculate that most of the homeless are eligible, they argue that barriers such as documentation of identity or administrative burdens prevent many from participating. The difficulty of making effective use of food stamp benefits without adequate cooking and storage facilities is also a barrier. While the Food Stamp Program does permit states to contract with restaurants to serve meals at concessional prices to the homeless, such authorizations are uncommon among states.

**HORS D'OEUVRES.** See **Dinner; Meal.**

**HORSE.** For the last five thousand years, the horse has of been of greater human interest for its strength than as a source of meat. The domestication of the horse is considered to have taken place in the present-day Ukraine in the fourth millennium B.C.E., and the practice spread from there. Prior to that, wild horses had been caught for food and seem to have been eaten by most peoples that adopted them during the first three thousand years of their domestication, though other, work-oriented kinds of use were more important.

The people of ancient Greece and Rome despised horse eating, although it was still practiced among the Germanic peoples and Asian nomads at that time. The Asian nomads also made a common use of mare's milk and "koumiss"; in fact, fermented mare's milk has been

Title page of the first cookbook to deal with the preparation and cooking of horse meat. It was written by Henriette Davidis, one of the most popular cookbook authors of nineteenth-century Germany. The book was issued during a period of widespread famine and political upheaval. COURTESY OF HANS WEISS. ROUGHWOOD COLLECTION.

an important foodstuff in the steppes of Central Asia and is still a common drink there, and is also known in Scandinavia and the former Soviet Republics. Boeuf tartar is believed to originate from Asian Nomads, who preferred horsemeat to beef and therefore many think that this dish was originally made from horsemeat. Horsemeat is still an important food in Mongolia and Japan. The Japanese like to use it in their famous teriyaki. Horses are bred for food in many places in Asia, as in Mongolia, Central Asia, and Japan.

The dietary restrictions of Jews, Muslims, and most Hindus do not allow horsemeat in the diet. The practice of sacrificing horses and in some cases consuming their meat has been widespread in Europe and South Asia from the beginning of their domestication. It was part of pagan Germanic ceremonies and its importance in pagan religion is probably the reason why it was despised by Christians. Horsemeat is the only foodstuff that Christianity has abolished from the diet for religious reasons. Canon law forbade the eating of horses, and most of the Christian societies in Europe adopted that ban. This ban was for the most part abolished in first half of the nineteenth century in the Christian countries of Europe. Now horsemeat is eaten in most of the European countries, and in France, Belgium, Italy, Switzerland, and Iceland horses are bred for food production, although horse has not yet become a considerable part of the diet in any of these countries. The French and Flemish consume the most horsemeat in Europe, but the highest rate of consumption has amounted to only about five percent of that of beef. In the last decades of twentieth century the consumption of horsemeat dropped. One reason was that meat was cheaper when it was a byproduct of raising horses for uses that machines have mostly taken over now. Another reason is the increased opposition to eating horsemeat by animal rights activists. Activists in the United Kingdom have fought against eating horsemeat for decades, and in America the campaign against horse slaughtering for food is also prominent. Some American Indians are traditionally horse eaters, but the average consumption in the United States is low, although horsemeat is readily available. French immigrants make up a considerable part of the horse eaters. In many places in the Americas, as in the United States (the leading producer of horsemeat), Argentina, and Canada, horses are bred for their meat but it is mostly exported.

Horsemeat is darker red than beef and venison. Raw horsemeat is also more fibrous, and if kept for a while, it becomes rapidly black in color. It is more than 50 percent lower in fat and energy than beef, but of comparable nutritional value. After slaughter, foals and horses up to about two years old are usually chopped and prepared in ways similar to cattle and served as various kinds of steaks and goulashes, although special recipes for horsemeat are rare in the cookbooks of the Western world. The meat is easy to digest and the taste generally falls somewhere between beef and venison but a bit sweeter than either. Meat of older horses is commonly salted, smoked, or made into sausages. It can be very difficult to distinguish foal meat and beef, if it is spiced the right way. Hence in many places measures have been taken to prevent selling of horsemeat as beef. Older horses tend to be fatter, and horsefat is yellowish in color and not considered good in taste. The horsefat gets quickly rancid if not properly conserved, and horsemeat deteriorates more rapidly than beef. The fat, when melted, becomes oillike, and has been used for bread baking in northern Europe.

**HORTICULTURE.** Horticulture, literally garden culture, is a part of crop agriculture that also includes agronomy and forestry. By tradition, horticulture deals with garden crops such as fruits, nuts, vegetables, culinary herbs and spices, beverage crops, and medicinals, as well as ornamental plants. Agronomy is involved with grains, pasture grasses and forages, oilseeds, fiber crops, and industrial crops such as sugarcane, while forestry is involved with trees grown for timber and fiber as well as the incidental wildlife. The edible horticultural crops are used entirely as human food and are often utilized in the living state and thus highly perishable. In contrast, edible agronomic crops are often utilized in the nonliving state, are highly processed, are often used for animal feed, and usually contain a high percentage of dry matter. The precise distinction between horticultural and agronomic crops is traditional. In general, horticultural crops are intensively cultivated and warrant a large input of capital, labor, and technology per unit area of land, but in modern agriculture, horticultural crops may be extensively grown while many agronomic crops are now intensively cultivated. Many crops are claimed by more than one discipline. Horticulture is practiced in large agricultural operations, in small farm enterprises, and in home gardens.

#### Horticultural Arts

Horticulture is associated with a number of intensive practices that collectively make up the horticultural arts. These include various propagation techniques incorporating special plant structures such as bulbs, corns, or runners; the use of layers or cuttings; budding and grafting; and micropropagation involving tissue culture. Cul-

tural practices include soil preparation, direct planting or transplanting; fertilization; weed, disease, and pest control; training and pruning; the use of controlled environments such as greenhouses or plastic tunnels; applications of chemical growth regulators; various harvest and handling methods; and various postharvest treatments to extend shelf life. Other practices associated with horticulture are breeding and genetic techniques for crop improvement, marketing methods, and food processing. Ornamental horticulture, not considered here, includes added practices associated with landscape architecture and the floral arts. While horticulture is an ancient art with many of its practices empirically derived, present-day horticultural arts are intimately associated with science, so that modern horticultural science is one of the most advanced parts of agriculture. Recently some horticultural growers have attempted to reduce or even eliminate reliance on inorganic fertilizers and pesticides through the incorporation of ecologically based practices (integrated crop management).

### Horticultural Food Crops

Horticultural food crops include an enormous array of species that are grouped in various ways.

**Fruits.** Fruits of woody perennial plants have long been prized for sources of refreshment, for their delightful flavors and aromas, and as nourishing foods. Fruit crops can be defined as temperate, subtropical, and tropical depending on their temperature requirements. Temperate fruits are deciduous (drop their leaves in the cold period) and undergo dormancy requiring a certain amount of low temperatures (chilling period) before growth is resumed in the spring. Subtropical fruits require a very short chilling period. Tropical fruits are usually evergreen and are extremely cold-sensitive. Within these groupings fruit crops are usually grouped by taxonomic affinity. The temperate fruits include the pome fruits (apple, pear, quince, medlar), stone fruits (apricot, cherry, peach and its smooth-skin variant the nectarine, and plum), vine fruits (grape and kiwifruit), and small or bush fruits (strawberry; blueberry, cranberry, and lingonberry; brambles such as blackberry, raspberry, and various hybrids; currants and gooseberries). The subtropical fruits include citrus (citron, grapefruit, the tropical pomelo, sweet orange, lemon, lime, mandarins, and various hybrids such as the tangor or tangelo); and fruits associated with Mediterranean climates (avocado, cactus pear, carob, fig, loquat, persimmon, pomegranate). There are hundreds of tropical fruits, of which the most important are banana and plantain, mango, papaya, and pineapple, but there are hundreds of others with regional interest, including acerola, akee, carambola, cherimoya, durian, guava, litchi, mangosteen, passion fruit, rambutan, sapodilla, and soursop.

**Nuts.** The important tree nuts that enter into international trade include almonds, Brazil nuts, cashews, chest-

### CROP PROPAGATION

Horticultural crops are multiplied sexually (seed propagation) or asexually (clonal or vegetative propagation). Many vegetables and herbaceous (soft-stemmed) ornamentals are seed-propagated (beans, tomato, petunia). However, some seed is produced by nonsexual means (apomixis—bluegrass, many citrus, mango), and plants produced by this type of seed are considered vegetatively or clonally propagated. Clonal propagation occurs naturally in many horticultural crops through special vegetative structures such as the tubers of potato, the runners of strawberry, the cloves (corms) of garlic, or the bulbs of tulip. Clonal propagation can be achieved by cuttings, where pieces of the plant regenerate missing parts. Thus, shoot cuttings regenerate roots (grape), root cuttings regenerate shoots (sweet potato), and leaf cuttings regenerate shoots and roots (African violet). Most fruit crops are propagated using grafting techniques where plants are physically joined together, in which the combination of parts achieves physical union through tissue regeneration to grow as a single plant. The part of the combination that provides the root is called the stock; the added piece is called the scion. When the scion consists of a single bud only, the process is referred to as budding. A modern form of vegetative propagation is called micropropagation and involves tissue culture—the aseptic growth of cells, tissues, or organs in artificial media.

This technique permits very rapid propagation and is widely used for many foliage plants. It is commonly used to produce disease-free stock of strawberry, which are later propagated in the field by runners.

nuts, hazelnuts, macadamias, pistachios, pecans and hickories, and walnuts.

**Beverage crops.** Beverage crops include the subtropical crops—coffee, tea, and maté—and the tropical cacao used for cocoa and the confection chocolate.

**Vegetables.** Vegetables are typically herbaceous (soft-stemmed) plants in which various parts are used as food, including roots, tubers, leaves, fruit, or seed. There are various groupings based on the part consumed and taxonomic affinity. Vegetables include the root crops (beet, carrot, cassava, celeriac, dasheen, horseradish, parsnip, potato, salsify, turnip, radish, rutabaga, and sweet potato, as well as some little-known Andean tubers such as oca, mashua or anu, and ulluco, and root crops such as arracacha, maca, and yacon); bulb or corm crops including the pungent alliums (chive, garlic, leek, onion, shallots,

## PLANT DOMESTICATION

The greatest advances in horticulture, the selection and domestication of our useful crops, were made in prehistory by farmers unknown and unsung. The basic techniques of horticulture were well established by ancient cultures in antiquity (5000 to 1500 years ago). In fact, a complete record of horticulture practices is illustrated in the tomb artwork of ancient Egypt. The horticultural technology of antiquity includes basic propagation techniques (seed handling, grafting, use of cuttings); planting and cultivation (plowing, seed bed preparation, weeding); irrigation technology involving water storage, lifting, and channeling; storage technology such as granaries; fertilization and crop rotation; plant selection; basic food technology (fermentation technology in bread- and winemaking, drying, and pickling), and even the beginning of protected culture (the Romans had a primitive greenhouse using mica for cucumber forcing).

and chive); salad or leafy crops (arugula or rocket, celery, chicory, cress, endive, lettuce, parsley); cole crops or crucifers (cabbage, cauliflower, broccoli, brussels sprouts, kohlrabi, Chinese cabbage, and various Asian types such as bok choy); potherbs or greens (chard, collards, dandelion, celeriac, kale, mustard, orach, spinach, New Zealand spinach); solanaceous fruits (eggplant, sweet and hot peppers, tomato and husk tomato), cucurbits, also known as melon or vine crops (chayote, cucumber, muskmelon, pumpkin, squash, watermelon); legumes or pulse crops in which the seed is consumed (adzuki bean, broad bean, chickpea, common bean, cowpea, lima bean, mung bean, rice beans, tepary bean, urdbean, garden pea, and pigeon pea). Some vegetables are perennial (artichoke, asparagus, Jerusalem artichoke, rhubarb, sea kale). Some agronomic crops are consumed as a vegetable in various stages, and these types are included as horticultural crops. Examples include sweet corn (the immature ears of a sweet type of maize), immature vegetable soybean or edamame, and the young leaves of amaranth.

**Culinary herbs and spices.** Aromatic plants used for culinary purposes are called herbs when they are temperate species and spices when they are tropical. Examples include allspice, anise, basil, capsicums, caraway, cardamom, cinnamon, chervil, clove, coriander, cumin, dill, fennel, funugreek, garlic, ginger, laurel, marjoram, mint, mustard, nutmeg and mace, onion, organum, parsley, pepper, poppy seed, rosemary, saffron, sage, savory, sesame, star anise, tarragon, thyme, and turmeric.

## Horticultural Societies

The field of horticulture has a great many organizations and societies devoted to all phases of horticulture, including amateurs and fanciers, growers and handlers, researchers, and academics. There are plant societies devoted to individual or groups of crops, trade organizations devoted to the production and marketing of individual horticultural crops, and scientific societies devoted to scientific research. In the United States, the principal society devoted to the science of horticulture is the American Society for Horticultural Science (founded 1903) with offices in Alexandria, Virginia. The society publishes three scholarly journals as well as books, and conducts annual meetings. Examples of other scientific societies in the United States include the American Pomological Society, devoted to fruits and nuts, and the American Potato Society. Growers of horticultural crops are also organized in state societies. Many countries have a national scientific society devoted to horticulture. The International Society for Horticultural Science located in Leuven, Belgium, sponsors international horticultural congresses every four years.

## Horticultural Education

Horticulture is a recognized part of the curricula in agriculture worldwide. In the United States many land grant universities have horticulture departments devoted to undergraduate education leading to the B.S. degree. Most of these departments provide advanced training leading to the M.S. and Ph.D. degree. However, since the 1990s

## THE MORRILL ACTS

The land-grant universities trace their origins to the Morrill Act signed by Abraham Lincoln in 1862, a famous piece of legislation sponsored by Justin Smith Morrill of Massachusetts. Monies from the sale of public lands (30,000 acres for each of its Senate and House members) were to be used as a trust fund to endow a college where practical education in agriculture and engineering would be emphasized. The Agricultural Experiment Stations associated with the land-grant colleges trace to legislation (Hatch Act of 1887) sponsored by William H. Hatch of Missouri. In 1890, the Second Morrill Act was passed and provided direct annual appropriations and forbade racial discrimination in admission to colleges receiving the funds. States were allowed to escape this provision if separate institutions were maintained and a number of the "1890 colleges" in various states open to African Americans became known as "black colleges."

The bounties of horticulture are celebrated in this still-life painting by French artist Hippolyte Chaignet. Collection of the Musée des Beaux-Arts. © ARCHIVO ICONOGRAFICO, S. A./CORBIS.

there has been a trend for horticulture and agronomy departments to combine into either a Crop Science or Plant Science department. A number of schools give two-year programs leading to associate degrees.

**HOUSEHOLD.** Definitions of what constitutes a household have always been dynamic and dependent on political, historical, and cultural factors. Prior to the nineteenth century, typical households were large and agriculturally self-sustaining, with most family members contributing to homestead productivity. The industrial revolution in Europe and the United States brought about changes in household and family structure that influenced fertility patterns and household size, including changes in gender roles and definitions of modernity.

The contemporary American household continues to change in composition and size. Married couples comprised 78 percent of households in 1950, but this percentage dropped dramatically over the next forty years to a low of 53 percent in 1998. The average size of the American household has also decreased in recent years. Over half of American households (57 percent) now consist of only one or two people, compared to an average of 3.1 persons in 1970 (USDS, 2001).

Other nations have also experienced rapid shifts in household size and composition. In their 2000/2001 General Household Survey, the National Statistics Office of Britain reported a doubling and tripling, respectively, of one-person and two-person households between 1971 and 2000. The percentage of married-couple households with dependent children dropped from 31 percent of all households in 1979 to 21 percent in 2000 (Walker et al., 2001).

The basic definition of "household" given by the U.S. Census is "all the persons who occupy a housing unit." The only qualification is that there can be no more than eight persons not related to the head of the household; the unit then becomes "group quarters" (USCB,

1999). Another governmental definition of household, determined by the Food and Nutrition Service (FNS) division of the U.S. Department of Agriculture, is "individuals who live in a residential unit and purchase and prepare food together." This definition plays an important role in the Food Stamp Program, as the household is the basic unit on which benefits are granted. According to Food Stamp Program policy, people who share a housing unit but do not prepare and purchase food together are not considered a household. Thus, food is a crucial component of the Food Stamp Program's definition, even if not of that of the U.S. Census.

Food also plays a role in how other countries define a household. In the view of the Swiss Household Panel, one criterion that defines a household is whether household members share a meal at least once every week. Anthropologists and others often define a household in terms of food preparation and consumption: all individuals who consume food from one hearth belong to a household. Central to this is the idea of "commensality," or food sharing, and anthropologists have often documented the key role of food in the formation and maintenance of social relations both within the household and beyond. Nutritionists and economists have often used the household as a primary unit of analysis. While the household appears to be a "natural unit" for studies of food consumption and nutrition, this conceptualization poses a problem in many parts of Africa and Asia where households are polygamous or where "extended family" households are common.

Anthropologists are increasingly engaged in the examination of household dynamics, focusing on social interactions, marital-sexual power relations, and work or food allocation. Recent research has shown that household composition and size can play a considerable role in dietary intake and distribution. In some settings or cultures, particularly where food resources are insecure, gender or age discrimination may result in unequal food distribution among some household members.

Many cultures also assign significantly different positions and/or status levels to males and females. The types of high-social-value foods vary between cultures, but depending on the kind of food, its restriction could have significant nutritional implications for one gender or the other. Some cultural groups, such as the Chagga of Tanzania, have distinct food prescriptions and proscriptions for men and women. Males are proscribed against eating green vegetables, so females in households are ultimately the only members consuming these foods. Other societies may prohibit women from receiving foods considered to be of high social value, such as meat or animal products, particularly during pregnancy or lactation. However, these cultural norms of proscription or prohibition do not always reflect behavioral adherence. Women denied meat may be at higher risk for protein and iron deficiencies. In rural Nepal, unequal food distribution and cultural beliefs were shown to influence

inadequate micronutrient intakes by women, and plate-sharing within households was protective among children for mild xerophthalmia, a clinical deficiency of vitamin A. Cultural beliefs, then, can influence both positive and negative nutrition and health outcomes.

To investigate nutrition and health status within and across households, it is important to understand the complex interrelationships of the overall environment. This is the strength of a biocultural approach that situates individuals and households within specific cultural and social settings.

**HUMOR, FOOD IN.** Humor and laughter are unique to humans and separate them from other animals. While all social and cultural aspects of human existence are subject to humor, food and sex are the most widespread topics because they are the fundamental biological bases of human existence. Food habits and sexual practices show considerable cross-cultural variations.

Food is a handy weapon for humor on the stage. Actor Bert Lahr is seen here cooking (with a pinch of Old Dutch Cleanser) on stage during a performance of *George White's Scandals* at the New Amsterdam Theatre in New York. © JOHN SPRINGER COLLECTION/CORBIS.

People in different cultures have definite views not only of the foods they eat but also of what constitutes a potential food. Ethnocentrism reigns supreme in matters of food and food habits.

Humor in individual societies targets food and eating habits while humor at the universal level focuses on cross-cultural differences in food habits, food values, and ideologies. No single comprehensive, cross-cultural treatment of food-related humor exists, although there is an extensive literature on the foods and food habits of people in specific societies. This essay discusses the humor of food, primarily in the United States.

#### Forms, Techniques, and Topics of Food-Related Humor

Verbal and nonverbal humor is primarily based on incongruity and takes various forms: jokes, puns, riddles, funny stories, parodies, ludicrous definitions, malapropisms, one-liners, caricatures, cartoons, pranks, and practical jokes. Cartoons and caricature generally use visual humor while pranks and practical jokes exploit social situations. However, almost all types of humor depend on language. The techniques used in humor are exaggeration, ludicrous imitation, reversal and contrariness, and

Food has always been an easy target for humor. This spoof on cookery and dining manners was sold at New York newsstands as a Christmas joke book in 1890. It contains several chapters on various branches of cookery, including recipes. ROUGHWOOD COLLECTION.

trivializing everyday life events. Topics include genuine and fictional recipes; fast-food and other restaurants; chefs and fast-food cooks; butchers, housewives, waiters, and customers; cooking processes; eating habits of various ethnic groups; food ingredients; and eating utensils.

### Jokes

Jokes are the most popular type of food humor. Jokes take many forms and include other types of humor. They include riddles, one-liners, word play, ethnic jokes, and so on. A major characteristic of jokes is the surprise punch line. Over the last fifty years, many collections of all types of jokes have been published. The introduction of the Internet has helped disseminate thousands of jokes all over the world. There exist Internet "The A-Z Jokes Collections" and new jokes are added daily.

Jokes either exaggerate or overturn common cultural practices, and target cultural roles and professions related to cooking and eating, making them incongruous. Jokes

focus on the contradictions between cultural perceptions of ideal recipes, appropriate food habits, and roles, on the one hand, and social reality on the other. Among jokes relating to food professions, those relating to waiters are especially popular, and the question-answer format is most common. Generally, waiters provide the punch line by their culturally inappropriate and incongruous answers to customers' complaints.

### Pranks and Practical Jokes

Pranks and practical jokes are an important aspect of all informal and formal social interactions. Generally, individuals, but occasionally groups, are the butt of these jokes, especially at parties, weddings, and other similar social gatherings. The aim is to surprise and embarrass the chosen target, and this is accomplished through unexpected actions such as a pie in the face, removal of some clothing thereby revealing "private" body parts, pouring water or liquor on a person or a group of people, or throwing smelly foods at the victim(s). Some pranks are so well established in the United States that the victims expect them, thereby canceling the element of surprise. A popular ritual in the United States is a "roast," a banquet in honor of a celebrity who is subjected to humorous tongue-in-cheek jibes and insults by friends. The target is figuratively roasted until he or she is totally embarrassed, to the amusement of the participants.

### Cartoons

Cartoons are a very widespread and popular form of humor. In the United States, daily newspapers are full of cartoon strips, many of which focus on food. The two best known are "Blondie" and "Beetle Bailey." Blondie's husband Dagwood is famous for his appetite and huge sandwiches. The waiter and the cook at the diner where Dagwood eats his lunch are also humorous characters. The catering business started by Blondie has led to several hilarious episodes. While "Sarge" in the Beetle Bailey cartoon strip is known for his gluttony, the army cook is notorious for his awful cooking, and his food is disliked and made fun of by the soldiers. The "Far Side" cartoon series by Gary Larson has had several food-related cartoons, especially episodes which depict anthropologists being boiled in the cauldron by wild tribes. Jack Ziegler's cartoon collection "Hamburger Madness" demonstrates the zany aspects of fast food. The cartoons on the front and back covers portray the ubiquity of hamburger in the world.

### Caricatures and Parodies

Caricature and parody involve creatively ludicrous imitations of aspects of food, emphasizing the contrast between its serious and trivial aspects. Humorous cookbooks (to be discussed below) caricature diners, chefs, utensils, gadgets, and cooking itself. While caricature emphasizes the visual attributes of its subject, parody focuses on language and style. It is the incongruity between the

## HOT DOGS AND NEGATIVE STEREOTYPES

Americans have always had a strong negative reaction to members of some Asian societies who eat dog meat. This has much to do with the American cultural belief that one does not eat pet animals. Yet one of the most popular fast foods in the United States is named the “hot dog.” How did this come about? Why do Americans call the food in question by this name when they intensely dislike the idea of eating dogs? And why is this name readily accepted? One could say, after all, “what’s in a name?” But we all believe that names are important. People have a general belief in the magical ability of words. Even many Americans who do not believe in the power of words want to know when they visit a physician what they are suffering from, and they are satisfied only when the physician actually names their illness. Hence the puzzle and the irony of the name “hot dog.” It is true that hot dogs do not contain dog meat. But it is interesting to contemplate how the name originated and how it became widespread. Hot dogs are also known as frankfurters and wieners. They are a type of sausage. J. J. Schnebel (at “hot dog” in “Who Cooked that up?” <http://members.cox.net/starview/>) provides a brief history of this food from the time of the ancient Greeks through the Middle Ages to modern America. The names “frankfurter” and “wiener” are derived from the names of the two European cities, in which sausages were manufactured and were a popular food item: Frankfurt in Germany and Vienna (Wien) in Austria. This food was also called “dachshund sausage” because of the similarity of its shape to the German dog used in hunting badgers; thus the word is a combination of two German words, *hund* meaning hound and *dachs* meaning badger. The name continued to be used by German immigrants who began to sell these sausages in New

York City in the 1860s. These sausages gradually became popular as fast foods to be served at picnics, and to be consumed for a quick lunch on the street, in restaurants, and at baseball games.

Schnebel credits the sports cartoonist Thomas Dorgan of the *New York Journal* for inventing the name “hot dog.” Dorgan wanted draw a cartoon of a “barking” sausage steaming in its roll—which was until then known as dachshund sausage—being eaten at baseball games in New York. He did not know the spelling of the word “dachshund” so instead he used “hot dog” and the name caught on.

The joke below titled “Americans Eating Dogs” illustrates how ethnic stereotypes are mutual, with an added twist emphasizing the similarity of a hot dog to the male organ of procreation in humans and many other animals.

Two foreign nuns have just arrived in the United States by boat and one says to the other, “I hear that the people of this country actually eat dogs.”

“Odd,” her companion replies, “but if we shall live in America, we might as well do as the Americans do.”

Nodding emphatically, the Mother Superior points to a hot dog vendor and they both walk toward the cart.

“Two dogs, please,” says one.

The vendor is only too pleased to oblige and wraps both hot dogs in foil and hands them over the counter. Excited, the nuns hurry over to a bench and begin to unwrap their “dogs.”

The Mother Superior is first to open hers. She begins to blush and then, staring at it for a moment, leans over to the other nun and whispers cautiously, “What part did you get?”

serious and trivial that is amusing. Asian cultures that emphasize food rituals are often subjected to such parodies. Television has occasionally emphasized caricature in regularly featured cooking shows. In the United States there is now a twenty-four-hour channel devoted to cooking shows, some of which tend to lean toward caricature.

Sitcoms have their share of the humor of cooking, involving episodes where inept men and woman take a stab at cooking and end up in total chaos. Fun is also made of exaggerated rituals connected with selling and buying ready-made food. The episodes of the “Soup Nazi” in the popular sitcom *Seinfeld* are worth noting here. Customers have to stand in line, politely ask for the kind of soup they want, pay the right change, and move to the side in a drill-like fashion. The cook and proprietor named the “Soup

Nazi” by the main four characters in the show can, and does, refuse his soup to anyone who does not obey this ritualistic etiquette or displeases him in any way. Yet, people line up outside his joint to taste his soup. The *Seinfeld* episodes devoted to this theme and involving the four major characters are hilarious.

Well-known food dishes and their names are subject to parody that works both ways. Known foods and recipes, and other food-related events, actions, states, and so forth are manipulated to sound like famous book or movie titles and these, in turn, are altered to remind the readers of famous recipes, as illustrated in *To Grill a Mockingbird And Other Tasty Titles*, concocted and illustrated by Ruth Young and Mitchell Rose. A few examples from it are “The World According to Carp,” which is described

## WAITER JOKES

Among all food jokes, the most popular seem to be those making fun of waiters. Such jokes portray waiters as rude and not interested in the orders and complaints of the customer; in other words, waiters are not seen as true professionals. However, these jokes also focus on the presumed ability of waiters to answer any customer complaints with witty and unexpected one-upmanship, thereby creating an incongruous situation. The preferred format of waiter jokes is question and answer. The following are a few examples.

1. Customer: Waiter, there is a dead spider in my soup!  
Waiter: Yes, Sir, they can't stand the boiling water!
2. Customer: Waiter, waiter, there is a fly in my soup!  
Waiter: Not so loud, Sir, everyone will want one!
3. Customer: There is a small slug in my salad!  
Waiter: Sorry, Sir, I'll get you a bigger one!
4. Question: Why do waiters prefer elephants to flies?  
Answer: Have you ever heard anyone complaining of an elephant in their soup?
5. Customer: Waiter, waiter, there is a spider in my soup!  
Send for the manager!  
Waiter: It's no good, Sir, he's frightened of them too.

as "Smash nationwide bestseller by a writer's writer! Meet T. S. (Terribly Salable) Carp, porpoiseful young novelist, and discover the best love story New England has produced since "Ethan Fromage"; "Lady Chatterley's Liver"; "Moby Duck"; and "The Soufflé Also Rises." The illustrations accompanying each tasty title are exaggerated and amusing.

Imaginary food recipes focusing on the personality traits of famous people are favorite areas of food humor. This kind of humor is difficult to categorize, although it probably comes under the heading of parody. *Freud's Own Cookbook* by James Hillman and Charles Boer (1984) and *Jean-Paul Sartre's Cooking Diary* (author unknown) are two such examples. The first describes such dishes as "Slips of the Tongue in Madeira Sauce" (p. 48), "Erogenous Scones" (p. 75), and "Incredible Oedipal Pie" (p. 76), that are reminiscent of concepts developed by Freud and his friends and colleagues. The Sartre book consists of philosophical musing about cooking and recipes.

## One-Liners, Puns, Riddles, and Word Play

These closely related and occasionally overlapping genres of humor are devoted to comments about common-sense rules of eating, dieting, low-calorie foods, overeating, obesity, food fads, and favorite, and addictive, foods of individuals and groups. Incongruity is the result of such techniques as reversal, exaggeration, and double meaning. Note the following: "Eating should never make you sad, unless it is a mourning meal"; "Visibly upset from the whole ordeal, the grape juice started to whine"; "I used to work at the sugar packaging factory. Then my position was dissolved"; "The upper crust of society is composed of a lot of crumbs held together by dough"; "If you eat something, but no one else sees you eat it, it has no calories."

Consumption humor is contrary to the common-sense constraints concerning what to eat and how much. Everyone has particular food addictions and many believe in the dictum of living to eat rather than eating to live! Humor focuses on such shortcomings. Note these one-liners: "If we are what we eat, then I am easy, fast, and cheap"; "A balanced diet is a cookie in each hand"; "No one thinks of any 'rules' associated with the when, where, and how chocolate should be eaten." We have the riddle: "Q.: Why is there no such organization as Chocaholics Anonymous? A: Because no one wants to quit eating chocolate."

Humor associating food with various aspects of human anatomy and sexual activities is widespread and popular. For example: "Q: What did one strawberry say to the other strawberry? A: If we hadn't been found in the same bed together we wouldn't be in this jam!" Note "The Life Story of An Egg": "So you think your life is bad, then just think how bad the life of an egg is. . . . You only get laid once. You only get eaten once. It takes four minutes to get hard and two minutes to get soft. You have to share a box with eleven other guys. And the only chick that ever sat on your face was your mother!"

Dictionaries of food items and related terms with creatively outrageous or absurd meanings are another type of humor, as illustrated by *A Cook's Dictionary* by Henry Beard and Roy McKie. They "bring new meaning to matters of taste." The very definition of the word "cooking" on the cover page is given as "1.n. the art of using appliances and utensils to convert ingredients and seasonings into excuses and apologies." A "chef" is defined as "any cook who swears in French," while "health food" is defined as "any food whose flavor is indistinguishable from that of the package in which it is sold." This dictionary also includes cartoon-style humorous sketches of food-related activities.

*Mahadev Apte*

**HUNGARY.** See **Central Europe**.

**HUNGER, PHYSIOLOGY OF.** Hunger is the set of internal experiences that lead a human or animal to seek food. Appetite describes the preferences that surround the selection of food that is found. For many people, hunger is a set of feelings often focused on the stomach. It may be associated with contractions of the stomach or intestine, and described as “emptiness.” Indeed, many of the early ideas about hunger and its opposite, satiety, were described in terms of stomach contractions or stomach distension. Increased physiological understanding has yielded the information that the stomach and intestine are only one part of the system experienced as hunger.

A drive to eat food can be produced by damage to selected parts of the brain, usually located in the hypothalamus near the pituitary. When this area is damaged, animals and humans become voracious eaters and become obese. This indicates that there are sections of the brain that can inhibit food intake that, when destroyed, fail to do this. Alternatively, there are other regions of the brain (lateral hypothalamus) where damage in either humans or animals produces reduced food intake and wasting.

The connections between what happens in the body and how the brain recognizes it have advanced by leaps and bounds since the 1970s. One of the first discoveries was that many of the same messages or signals that are found in the stomach and intestine are also found in the brain. These so-called gut-brain messages can serve to stimulate or inhibit feeding. As a general rule, the ones produced and released in the body tend to inhibit feeding. Thus cholecystokinin, a hormone that causes the gallbladder to contract, also inhibits food intake. This peptide works both in the body and when put into the brain. Another gut-brain hormone is ghrelin. In contrast to cholecystokinin, ghrelin stimulates food intake whether injected into the body or into the brain. The fat cells are another source of important signals for hunger. The most important of these sources is a hormone called

leptin. When this hormone is absent in either humans or animals, massive obesity results. When this hormone is given back, hunger immediately subsides, indicating the important role that this hormone plays in the control of hunger. The amount of leptin released from fat cells increases as the total body fat increases. It thus serves as a circulating marker for the level of fatness. Once in the circulation, leptin acts on the brain. Through a lock-and-key mechanism, leptin changes the formation of four other hormones in the brain that regulate eating. When leptin is high, the release of two peptides (neuropeptide Y and agouti-related peptide) in the brain is reduced and two other hormones (cocaine-amphetamine regulated transcript and proopiomelanocortin) are released. Acting in concert, this combination of hormones reduces feeding and relieves the sensations of hunger. Conversely, when leptin is low, the opposite situation occurs, and hunger develops along with the search for food.

Insulin is a second major hormone in the body that signals hunger. In diabetic patients who take insulin and tightly control their blood sugars, mild degrees of obesity frequently develop. Similarly, some of the drugs for treating obesity (sulfonylureas and peroxisome proliferator-activated receptor- $\gamma$  agonists) produce weight gains. One likely way this happens is through reducing blood glucose that in turn signals the need for food.

The role of circulating glucose in the initiation of hunger has been advanced considerably. Beginning with studies in animals, it was found that a small drop of about 10 percent in glucose preceded the onset of many but not all meals. When this drop in glucose was prevented, the animal did not eat at the expected time. That is, hunger had been prevented by manipulating glucose. The glucose-stimulated hunger can be provoked by giving a drug that mimics the key nerve (vagus) that supplies the pancreas to release insulin. Studies in human beings also found that a small drop in glucose preceded many meals. It has been long known that there were lock-and-key systems in the brain responding to glucose or its deficiency. The experiments described above suggest that the brain signals a small release of insulin that leads to a transient decrease in glucose, which in the “primed” animal produces an internal feeling of hunger.

These many signals for feeding can increase the intake of all available foods, or they can signal intake of certain foods. We know that when we have eaten our fill of turkey at Thanksgiving, there is still room for pumpkin pie or ice cream. The loss of hunger for one food after it is eaten is known as sensory specific satiety, that is, the overall drive to eat can be regulated in parts. This is consistent with the finding that some of the signals described earlier stimulate one type of food intake or another, but not necessarily all. Thus, some signals are known that will specifically reduce the intake of fat and others, carbohydrate.

Obesity results from changes in leptin or damage to the brain. From studies on the control of feeding, it is

known that at least two monamine neurotransmitters (norepinephrine and serotonin) in the brain play a particularly important role. These neurotransmitters have been the subject of considerable interest, since most of the medications used to treat obesity influence hunger through changing levels of one or both of these neurotransmitters. As more is learned about the control of hunger, a steady source of new targets is available that can be used to develop future medications for the treatment of obesity.

**HUNGER STRIKES.** The hunger strike is a type of political resistance notable for deploying deliberate self-starvation to protest alleged injustice and abuses of power. Food plays a central and paradoxical role in these acts by virtue of its conspicuous literal absence, yet compelling figurative presence. Hereby, the substantive rejection of material food comprises the main tactical strategy of hunger strikes, while the evocative symbolisms of food and food denial inscribe the moral messages conveyed by proactive martyrdom for a cause.

#### History and Political Agendas

Although the origins of hunger striking are obscure and its venerable history sketchy, it is known from diverse cultures and varying historical epochs dating back to antiquity. Hunger strikes were described in the lore of ancient India, and were well-established practices in medieval Celtic societies. In the early decades of the twentieth century, British suffragettes deployed hunger strikes to gain women's right to vote; and in the closing decades, hunger-striking Chinese students in Tiananmen Square petitioned for democratic reforms, and Tibetan monks

staged public fasts outside the United Nations to spotlight their struggles for self-determination. The hunger strikes of Mahatma Gandhi in British-occupied India, Andrei Sakharov in the Soviet Union, Nelson Mandela in apartheid South Africa, and Bobby Sands of the Irish Republican Army, made these individuals renowned in their respective days. In modern times starvation rebellions have been geographically widespread and have championed numerous political causes, ranging from wholesale indictments of totalitarian power to more localized claims for citizens' entitlements within late capitalist democracies.

Instances from the 1980s and 1990s include Chinese women seeking asylum in the United States on the grounds that the one-child policy (and consequent forced abortions) are a form of political persecution, Iranian refugees resisting deportation from France, Kurdish fasters in Turkish jails petitioning to be accorded political-prisoner status, Israeli physicians on hunger strike for better wages, and American activists lobbying to abolish homelessness. Hunger strikes have been directed against nuclear proliferation, unjust imprisonment, immigration policies, and military actions; and they have been undertaken to champion political sovereignty, environmental protection, education reform, animal welfare, and the rights of workers, farmers, and minorities.

#### Common Characteristics

As their mode of operation, all hunger strikes share in common the principles of nonviolence, a claim to martyrdom for a cause, and an appeal to a universalized ethics that aims to indict by shaming the opponent. Modern applications are further framed by their appropriation of democratic and human rights discourses, and by their potential to capitalize on the vast and rapid circulation of sensational spectacles in a global media network.

In general the issues that incite hunger strikes have either been failed by, or fall outside the purview of, official legislation. By necessity, then, these strategies are designed to circumvent conventional systems of jurisprudence. Nonetheless, in dramatizing an interrogation via a tacit appeal to a public "jury," the hunger strike is structurally analogous to courtroom trials, such that it can be said to function as a kind of "meta-judicial trial." This trial is launched when the hunger-striking protagonist declares self-starvation, and thereby extends his quest for justice in the vulnerability of existence. Such deliberate martyrdom puts the body in an escalating "state of emergency" that graphically tests the resolve of the activist while simultaneously attesting to the depth of commitment. Taking oneself hostage to endorse a political agenda in effect constitutes the initial accusation, or "prosecutorial gesture," whereby the characteristically private act of not eating paradoxically transforms into a public indictment of an (allegedly) unjust system and its overseers. Under conventional trials, language—in the

form of law codes and legal arguments—is the established tool of power and order. Yet, in the meta-judicial trials set in motion by hunger strikes, the authority of language is symbolically displaced, to be superseded by food as an alternative medium of communication. In other words, food provides a symbolic vocabulary in the political resistance movement that makes starvation (nonfood) a weapon of social reform.

### Food as Symbol

The meaning-making enterprise of hunger strikes strategically exploits the complex and contradictory significance of food, which has been ambivalently endowed with both positive and negative associations in numerous cultures throughout history. Complementary to its role as vital nourishment, food characteristically betokens hospitality and charity, commands an exalted status at major life events, and is a special marker of ideology and identity. Food's beneficence is encoded in language: for example, "com-pan-ionship" in English means "the sharing of bread," thereby etymologically connecting friendship to a fundamental staple of Western cuisine. In its constructive essence, then, food is a preeminent material catalyst of human sociality and a signifier of shared community. Given its multifaceted centrality in human relations, the repudiation of food by hunger strikers can be read as an analogical rejection of community. In the manner that putrid food is inedible and can provide no nutritional sustenance, an unjust society is deemed uninhabitable and can offer no political-moral integrity. This leads to the self-exile of the faster, voluntarily removed from the (allegedly) corrupt circle of sociality.

The refusal of food engenders moralistic messages. For, despite its widely celebrated virtues, it is the intentional abstinence from food that has long been considered a ritual of purification in many religious traditions. Moreover, such self-disciplining still sends ethical (as well as aesthetic) messages in contemporary popular culture. According to Judeo-Christian teachings, the transgression of eating the forbidden fruit launched humankind's original fall from paradise; and gluttony was considered foremost among the seven deadly medieval sins. Abstinence from food provided one escape from these beastly temptations of the flesh, and accorded a path to greater spirituality that placed fasters outside the inherently violent food chain of consumption. It is upon this pious path of nonconsumption that hunger strikers embark, seeking some claim to moral righteousness by virtue of their excess asceticism. The faster's refusal to incorporate food asserts the individual body as sacrosanct and autonomous, and (through the symbolic substitution of food for community) safeguards the boundaries of the self against infiltration by a demoralized system. Importantly, in the striker's brief moment in the public limelight, self-starvation functions as an emphatic character sketch that stages a contest of willpower and suffering in order to prove dedication. By association, these performances strive to pair the political faster with the moral connota-

tions that underlie willingness to sacrifice oneself for one's beliefs.

By ransoming the body as the battleground of resistance, the hunger strike seeks to redefine political issues as existential matters, and replace abstract rules with an impending crisis of life or death. Whether its diplomacy is better characterized as "nonviolent penetration of the heart" (to quote Gandhi) or as "political blackmail" (to cite his opponent, Viceroy Linlithgow), the act is one of keen, if nonetheless desperate, negotiation. Hereby, the violence fasters inflict on their own bodies (which are literally consumed by starvation) symbolically parallels the violence they contend power has inflicted on them (which "consumes" their moral integrity). The striker's purposeful hunger for food thus makes concrete an unfulfilled hunger for justice that can only be satisfied by a reformation of the political-moral order.

### Communal Bond

In the iconoclastic logic of the goal-oriented fast, such reformation begins with the private suffering of the martyr put forth as a call to collective action. Just as trespasses of justice are deemed to be public concerns, the individual in need (and in pain) is deemed to be a matter of collective accountability. The individual's need for food invokes a primary interrelationship, based on food sharing as an archetype of caretaking. Insofar as premeditated self-starvation delves into the corporeal conditions of existence, it attempts to forge the commonality of hunger (an experience, to some degree, familiar to all) into an elementary, alimentary bond between striker and spectator. This bond is offered as the foundation for a code of ethics that seeks to mobilize righteousness from mutual responsibility for one another's physical and moral well-being. To ignore a cry for justice (and/or food) is tantamount to a shameful rejection of human mutual dependency.

Hence, in mirroring the violence of power and challenging its humanity, political martyrs endeavor to shame the (proclaimed) perpetrators of injustice. Reliant on its audience, the hunger performance summons civil witnesses to participate in this shaming and speak out against abuses of power. Through this unconventional diplomacy, hunger strikers appoint themselves scapegoats who map the ethical trespasses of an errant society onto their sacrificial bodies (a move which provocatively advertises sociopolitical inequities as undeniably bodily concerns). Here, food symbolism—with its mercurial nature—reemerges. For the messages underlying these political rituals of transformation are consonant with the healing and nurturing significance of food, which, when blessed and shared (witness consumption of the scapegoat, the totem, the transubstantiated bread of communion) can be sustaining, as can society, when purged of corruption. An end to the political fast, and the striker's consequent return to the community of food sharing, symbolizes redemption of the collective moral good.

**HUNTING AND GATHERING.** Hunting and gathering, or more generally stated as foraging, can be defined as a mode of subsistence in which all food is obtained from wild resources without any reliance on domesticated plants or animals. This has been the dominant means of subsistence for 99.5 percent of the 2.5 million years of human existence. It was only in the last ten thousand years or so that people began to domesticate and produce food in some areas, while in other areas hunting and gathering continued up until the nineteenth and twentieth centuries. Within this time period and throughout the many different geographical regions that people inhabited, there has been tremendous variation in food consumption. We will examine some of the major geographical, cultural, and temporal trends within this great diversity, as well as some common misconceptions.

Among the most prevalent misconceptions are the following:

1. People relying on wild foods had to work constantly in order to obtain enough to eat, and thus had no time to develop the arts of civilized life. In reality, quantification of time use among contemporary hunter-gatherers living in comparatively harsh environments has demonstrated that even these foragers

spend only two to five hours a day in obtaining food, leaving far more time for leisure than "civilized" people have.

2. Hunter-gatherers are frequently on the brink of starvation and are generally malnourished. In contrast to this view, recent studies have shown that most hunter-gatherers experience infrequent famines and are generally better nourished than neighboring or comparable agriculturalists due in part to the wider variety of foods that hunter-gatherers usually obtain and the lack of reliance on the narrow range of starch-rich plants that tend to typify agricultural and horticultural societies.
3. Hunting was the predominant source of food for hunter-gatherers. In fact, except for Arctic and Subarctic areas, plant foods were the most abundant and reliable foods and provided most of the daily fares (see Lee and DeVore 1986, Hayden, 1981). Surprisingly, hunters in most hunter-gatherer societies only manage to kill a few large game animals (over 10 kg) per year (Hawkes et al., p. 687).
4. Meat has a higher caloric value than vegetable foods. In fact, they are often of equal value (Eaton et al., p. 80).
5. Meat was always hunted. However, large proportions of the meat obtained even among contemporary hunter-gatherers is scavenged from kills of other animals.
6. Meat was the major goal of hunting. In reality, fat is much more important (Hayden, 1981; Speth and Spielmann).

One example is seen among the Australian Aborigines, who, after bringing down a kangaroo, cut open the abdominal cavity of the animal in order to determine the fat content. If there is insufficient fat on the animal, it is not eaten but left in the bush. Similar behavior is recorded in James Woodburn's film *The Hadza* (1966). There are also a number of accounts of hunter-gatherers who were starving despite the fact that they were eating large amounts of very lean meat. This is sometimes referred to as "rabbit starvation" in North America since it historically involved the reliance on lean rabbits by hunter-gatherers. Fat was critically important among hunter-gatherers for proper metabolism, for obtaining essential fatty acids, and for adequate calories to maintain body temperatures during cold periods.

While animals may not have been the major staple of most hunter-gatherer diets, ethnographically they were universally highly valued far above other types of foods. Successful hunting of animals conferred great status on individuals (Hawkes et al.), and hunting was almost universally carried out by men, while women and children gathered plants and small animals such as lizards, mice, or frogs.

## Evolutionary Trends

The origin of hunting is hotly debated. Wooden spears have been recovered from deposits over 400,000 years old, and reasonable arguments have been advanced for hunting going back to the Lower Paleolithic, some two million years or more ago. Other scholars argue that there was a prolonged period encompassing the Lower Paleolithic and perhaps the Middle Paleolithic, when people (proto-people) relied primarily on scavenged rather than hunted meat. There is little evidence for the use of plant foods from these early periods, but they undoubtedly played important roles in the overall subsistence diet.

Up until twenty thousand years ago or so, we must assume that all food was either eaten raw or was roasted on open fires (the initial use of fire is also disputed, but seems definitely to be in place by 400,000 years ago). Until the end of the Paleolithic, there is no evidence of boiling containers or the heating of rocks to boil liquids. Ethnographically, there appears to have been no hunter-gatherers that made any alcoholic beverages either.

It is only around twenty thousand years ago that fire-cracked rocks begin to appear and were probably used in boiling foods such as vegetables and the first bone soups (for extracting the bone fats). Some five to ten thousand years later, the first evidence for the systematic exploitation of a wide range of new food types appears. This includes the first evidence for grass seed use (grinders), systematic fishing (net sinkers, fishhooks, leisters, and fish remains), and semi-toxic nuts like acorns. The expansion of food resources used together with the new technological inventions that made this possible is sometimes referred to as the “Mesolithic” technology or exploitation pattern. It is this pattern that persisted in most areas of the world where hunter-gatherers survived until contemporary times.

## Choice of Foods

The choice of which plant, fish, insect, bird, and animal species were to be used for food was initially constrained by the regional environments that groups lived in and by the relative abundances at different trophic levels. In the Arctic, there are simply not many plant foods available for most of the year; in deserts, there are no fish; in each environment, the nature of the plants and animals will differ somewhat, but there will always be fewer (and more dangerous) carnivores than herbivores and more plants than herbivores. It is not possible or meaningful to catalog all such variations; however, it is possible to understand hunter-gatherer choices of foods in other ways using general trends or categories.

Although there is some variation between cultures in terms of what is considered to taste good, taste is frequently an important factor in determining which species are preferred to eat. Very strong-tasting flesh tends to be avoided (e.g., crows, mutton birds, mountain sheep [at least in the Northwest of North America]). Very fibrous

The nomadic Dayak peoples of Borneo hunt with blowpipes and preserve many features of a primitive lifestyle based on hunting and gathering. © CHARLES AND JOSETTE LENARS/CORBIS.

or woody plants are less desirable than those with more fleshy tubers or fruits. There are also many plants that are mildly toxic or produce undesirable effects when eaten in varying amounts.

Transcending these considerations, it has often been observed that species that are rich in fats, oils, starches, or sugars are avidly sought by hunter-gatherers. This appears to be due to the fact that high caloric foods are relatively rare in the wild. Wild animals are very lean during most of the year, averaging only about 4 percent fat versus the 29 percent fat content that is typical for domesticated animals (Eaton et al., p. 80). Bears are often favorite foods because they store large amounts of fat for winter hibernation; beavers are favored for the same reason. In southeastern Australia, streams were modified and canals constructed in order to capture large numbers of

migrating, oil-rich eels. Elsewhere, in eastern Australia, large gatherings of people occurred in order to harvest bushel loads of oil-rich moths in their mountain mating locations. In central Australia, witchity grubs were relished for the same reason, although only a few could be obtained at a time. Honey is another insect product greatly sought after by hunter-gatherers. Starch-rich tubers, nuts, and grains were also eagerly sought. In contrast to the more vegetarian agriculturalists of later times, salt does not appear to have been a major concern for most foragers, probably because of the natural salt content in the meat that they consumed.

There were also foods sought for more special dietary purposes. While berries might not provide many calories, they were often rich in vitamins necessary for good health. Keene has shown that the need for hides, vitamin C, and calcium were major nutritional bottlenecks among some groups of hunter-gatherers and that these considerations determined which animals and how many were hunted.

Some animals and plants were also avoided due to totemic or other cultural taboos. These might vary from individual to individual and from group to group. Some groups ate their domesticated dogs, others did not; the Tasmanians ate fish in their early prehistory, but avoided fish completely in their later prehistory. It is often difficult to discern any logic or pattern to these kinds of food prohibitions.

Finally, some scholars have tried to use optimal foraging theory to model hunter-gatherers' food choices. Winterhalder and Smith explain this theory, which postulates that resources that provide the best returns for the time and effort invested in their procurement and processing should be the most intensively used, and that all resources can be ranked relative to each other in these terms. The initial applications of this theory used caloric returns as the measure of theoretical desirability. Researchers attempted to calculate travel time, harvesting time, processing time, and caloric returns. The results did not fit the model expectations very well, but perhaps given all of the other factors that influence food choices (listed above), this may not be too surprising. In addition, risk factors probably play important roles. Food species that can be reliably obtained on a day-to-day basis may be preferred over foods that can only be obtained more sporadically, even if the reliable foods require more time and energy to obtain on average. Thus, plant foods, shellfish, and abundant small animals like lizards are sometimes the mainstays of hunter-gatherer diets while scarcer, more mobile types of food such as large game animals are eaten more episocially.

Of all the lower ranked food types requiring more effort, grass seeds constitute something of a special case. O'Connell and Hawkes observe that grass seeds are particularly inefficient sources of food in Australia, although many groups used them. It is therefore difficult to un-

derstand why they were used, and especially to understand why they only began to be used in the last fifteen thousand years or so of hunter-gatherer evolution. There are no seed grinding tools in the world archaeological record up to that time. Certainly, grass seeds contain starches, oils, and protein in desirable proportions. It is primarily the collection and processing costs that seem to have made this type of food unattractive, although some wild stands of wheat in the Near East can be harvested at the rate of one kg per hour as shown by experiments using Mesolithic type technology. One might expect the use of seeds for food to occur first in these more productive types of environments; however, it is curious that the Tasmanians never used grass seeds despite the occurrence of large seeded species similar to those in the Near East, whereas a number of Australian groups used several smaller seeded species. Various researchers have suggested that grass seeds may have begun to be used due to population pressures, or due to advances in processing and collecting technologies, or due to the emergence of prestige feasts, a topic to be pursued below.

### **The Effect of Food on Culture**

The nature of food resources used by hunter-gatherers has many ramifications for understanding their cultures. For most simple hunter-gatherers, or "foragers," wild food resources are scarce, fluctuating, and susceptible to overexploitation. Thus, population densities are very low (usually only supporting one person for every ten to one hundred square kilometers); group sizes are small (twenty to fifty people); the groups are nomadic (moving every few weeks to new resource areas); little if any food is stored; sharing food with others in the group is the normal (often obligatory) practice; intergroup alliances are formed to access refuges in times of famine; feasting is limited to sharing meat and fat from large desirable game animals; private ownership of resources and most other items is absent or rudimentary; borrowing is rampant; societies are comparatively egalitarian; and competitive or aggrandizing behavior is not tolerated (Hayden, 1993). This was probably the nature of most hunter-gather groups during most of the Paleolithic. In contemporary terms, the Hadza of East Africa and the Central Australian hunter-gatherers exemplify this type of adaptation.

Toward the end of the Paleolithic, and increasingly during the Mesolithic, there is evidence of dramatic changes in some of the richer environments of the world, especially along the richer riparian habitats and migration routes (whether terrestrial or marine). In the richest habitats, "complex" hunter-gatherers emerged. Population densities rose dramatically, groups became semi-sedentary or fully sedentary, storage of foods became important, new technologies appeared for obtaining and processing new species in massive quantities (especially fish, nuts, and seeds), large plant roasting pits occur for the first time (up to eight meters in diameter in the Northwest), prestige objects appear and testify to

private ownership of wealth as well as important socioeconomic differences, sharing is more limited, and debt-structured or competitive feasting emerged for the first time in human history. Northwest Coast cultures are perhaps the best examples of complex hunter-gatherers with their massive harvesting and storage of salmon, eulachon, halibut, or other fish species; their heavy use of shellfish; and their use of sea mammal blubber for feasting.

### Feasting and Domestication

Above all, as documented in Dietler and Hayden, it is the use of feasting to create debts, to obtain desirable goods and services, to craft political power, to establish close social relationships, and to transform surplus food production that is perhaps the most important turning point in the history of the use of food and in the evolution of human culture. Up until the development of surplus-based feasting, which provided sociopolitical and economic benefits, all animal species, including human beings, could only use as much food as they, or their co-residents, could eat themselves. This placed an absolute ecological limit on the utility of food. However, with the advent of feasting forms that conferred major advantages on hosts (such as better alliances, more [or more desirable] spouses, and more socioeconomic/political power), a new ecological paradigm was created without parallel in the natural world up until the emergence of complex hunter-gatherers. For the first time, as much surplus foods could be used (and transformed into other desirable items or relationships) as could be produced. This created an open-ended, positive-feedback relationship between resource production and practical benefits. The more that could be produced, the greater the sociopolitical and economic advantages that could be obtained; and the greater the sociopolitical or economic advantages, the more food could be produced; and so on. It is, above all, the establishment of this kind of positive feedback relationship through feasting that has most likely created the geometrically increasing rate of population, technological complexity, and political complexity that has characterized the past fifteen thousand years.

The establishment of feasts based on surplus production, and the host's desire to impress guests or make them beholden to him, may well have been among the factors responsible for the development of food production and the domestication of plants and animals some ten to twelve thousand years ago. Katz and Voigt have suggested, for instance, that cereal grains may have been domesticated primarily as a means of producing alcoholic beverages such as beer. In fact, there are no alcoholic beverages recorded for simple foragers, but it is possible that alcohol first began to be produced in the context of complex hunter-gatherer prestige feasting as among the Guditjmarra hunter-gatherers of southeastern Australia. On the Northwest (Pacific) Coast, there were certainly potlatches that featured starches (clover roots) and intoxicants (tobacco) as central parts of the feasts.

There are many other theories that purport to account for the development of domesticated animals and plants, such as climatic changes and population pressures. In support of the feasting and surplus model of domestication, it can be noted that among complex hunter-gatherers such as the Ainu of Japan, bear cubs were captured in the wild and raised for a year by wealthy families specifically for consumption at special prestige feasts. Moreover, domestic animals in traditional societies appear to be eaten exclusively in the context of feasts. Similarly, starchy clover roots and cinquefoil roots were tended and grown in Northwest Coast societies for use in feasting. In all these feasting contexts, the most prestigious foods are those with high lipid, starch, or sugar contents (fish oil, blubber, bear meat, deer fat, seeds, clover roots). These are the foods that were given to the most prestigious guests. These are the foods for which extra efforts were expended in order to produce. Rather than being forced by population pressures and famine to use foods that required great effort to produce, it may have been the importance of impressing guests at feasts that accounts for the extra efforts used to procure and prepare such low ranked but highly desirable foods as grass seeds, clover roots, and bear meat. This is especially true in complex hunter-gatherer societies where other more highly ranked foods are plentiful (e.g., in the Mesolithic/Epipaleolithic archaeological cultures of the Near East, and in the ethnographic Japanese and Northwest Coast cultures). The highly desirable foods used to impress important guests in complex hunter-gatherer feasts exhibit the same characteristics as those that were eventually domesticated and that we find in supermarkets today. The fruits are the largest, most succulent available; the vegetables are the least fibrous and highest in starches or oils; the meats have the highest fat contents. There is a world of difference between the use of foods by simple foragers and complex hunter-gatherers, and we are far more similar in our use of foods to complex hunter-gatherers than we are to the use of foods by simple foragers, even though the vast majority (99 percent) of our physical, mental, and emotional evolution occurred in the context of simple foraging.

## IBERIAN PENINSULA.

*This entry comprises three subentries:*

Overview

Portugal

Spain

### OVERVIEW

The Iberian Peninsula, in southwestern Europe, is occupied by Spain and Portugal. It is separated from the main continent by the Pyrenees and surrounded by the Atlantic Ocean to the northwest and west and the Mediterranean to the south and east.

The characteristics and features of Iberian cuisine cannot be understood without reference to the culinary influence of the Romans, Arabs, Jews, and Christians, and the dietary exchange that followed the conquest of America and colonialism in Africa and the Far East. However, Rome did not conquer the Basque country, and the Arabic heritage never reached the northwestern fringe of the Peninsula.

When former Muslim areas came under Christian rule, Muslims were forced to adopt Christianity. The expulsion of these so-called Moriscos from the Peninsula in the seventeenth century was the end of Moorish culinary system in Iberian lands. However, some Moorish elements are still discernible in Peninsular cuisine, particularly in regions where Moors or Moriscos remained for a longer time. These regions are Alentejo, Algarve, Andalusia, Aragón, Extremadura, Murcia, and Valencia.

### Contact between Moors and Christians

Moorish foodways influenced the cuisine of Christian upper classes during the Umayyad caliphate and Taifas' periods (tenth to twelfth centuries), during which Al-Andalus (the Iberian Muslim kingdoms) served as a cultural model. Secondly, there was a certain amount of cultural contact between Moors and Christians during long peaceful periods of time in frontier lands. Moorish culinary influence was also the product of years of interaction between Moorish and Christian communities in cities in which, after the Christian conquest, Muslims were confined to ghettos. Another point of contact between Muslim and Christian culture was through the

kingdom of Granada, the last Muslim territory in the Peninsula, conquered in 1492.

The Morisco rebellion in the kingdom of Granada (1568–1570), the relocation of the Granadan Moriscos around the kingdom of Castile, and their resistance to integration into Christian society despite the pressures of the Inquisition produced in Christians an aversion toward Moorish foodways. This aversion did not stop the culinary exchange, and, in fact, the influence of Christian culture and foodways on Moorish cuisine led to the disappearance of certain Moorish culinary practices. Often there was a substitution, addition, or different combination of ingredients and dietary practices. The outcome was a cuisine that contained some Moorish components but had different flavors, smells, colors, and textures.

### Moorish Culinary Contributions

Expiración García in *La Alimentación* (Food), Lucie Bolens in *La cuisine andalouse* (Andalusian cuisine), and Manuela Marín in *Cuisine d'Orient* (Eastern cuisine) have described Al-Andalus cuisine. However, contemporary Iberian cuisine has only a few elements of this Al-Andalus cuisine. In the Iberian Peninsula, these culinary features are marked by the prevalence or use of certain ingredients, dishes, methods of cooking, or ways of eating that were once typical of Al Andalus but devoid of any religious meaning. These features having a Moorish heritage are the following:

*Communal sharing from the same dish.* Examples of such shared dishes are paella, *migas* (fried breadcrumbs or semolina), and *gachas* and *papas* (porridges). This practice of sharing is no longer as prevalent as it once was.

*Predominance of yellow, green, and white colors.* Yellow is common in most rice dishes, in fish stews with rice or noodles, and in some chickpea stews. White is typical of some sweet rice puddings (*arroz con leche* and *arroz dulce*), some porridges, and some soups such as *ajo blanco* (a white garlic soup), the original gazpacho, *gazpachuelo* (a fish and egg soup), and various almond soups. Green is the dominant color of some Portuguese dishes prepared with coriander, although the *sopa verde* (green soup) cannot be included in this category.

*Use of saffron, cumin, and coriander.* Coriander is rarely found in traditional Spanish cuisine but is very popular in Portugal, especially in dishes from Alentejo; some food

writers relate this use to African influences. Saffron is used both to color and to flavor rice dishes, legume stews, and meat casseroles. Cumin seasons some legume stews, sausages, and dishes of meat or fish.

*Spiced stews made from chickpeas, lentils, and fresh or dried broad beans.* Examples of such legume and bean stews include *potaje de garbanzos*, *potaje de lentejas*, *fava rica*, and *favas con coentro*. The consumption of broad beans, however, has diminished during the last sixty years. Bulgur, or cracked wheat, is still included in some dishes from the Alpujarras region in Andalusia.

*Savory or sweet porridges, made from different grain flours.* These porridges, such as *gachas* and *papas*, were also the basis of Roman cuisine.

*Dishes made with breadcrumbs or slices of bread.* Breadcrumbs or torn-up slices of bread are used for thicken-

ing and giving texture to many varieties of gazpacho and other kinds of soups (*açorda*, *sopa de ajo*, *ensopados*, and *sopas secas*). Breadcrumbs are also the main ingredient in *migas*, a traditional and popular dish. There are some factors that relate the recipe for *migas*, in its Andalusian version, to the recipe for couscous. The first element is the way in which *migas* are cooked. A sort of steam cooking is produced through the sauteeing and continuous stirring of the semolina or the crumbs (these are previously soaked and drained) and gives a golden and granulated appearance to the dish. *Migas*, similarly to couscous, serve as the base for a wide range of other ingredients such as fresh fruit, fried vegetables, fried or roasted fish or sausages, and even sweets. Finally, *migas*, like couscous, are eaten from the pan in which they were prepared; the pan is placed on the table, and the whole family eats from it.

## A LINK BETWEEN *MIGAS* AND COUSCOUS

Southern Spain's *Migas*, a dish of sautéed breadcrumbs or semolina, are a derivative of couscous, a staple dish of steamed semolina. The following is an excerpt from *A Recipe from an Anonymous Andalusian Cookbook of the Thirteenth Century*, translated by Charles Perry:

I have seen a couscous made with crumbs of the finest white bread—for this one you take crumbs and rub with the palm on the platter, as one rubs the soup, and let the bread be neither cold nor very hot; put it in a pierced pot and when its steam has left, throw it on the platter and rub with fat or moisten with the broth of the meat prepared for it.

*Spiced fritters and desserts.* Various doughnutlike fritters (*buñuelos*, *boladinhos*, *roscos*, *filbós*, *pestiños*) and desserts (*alcorza*, *alfeñique*, *alajú*, nougat, and marzipan) are made by combining honey or sugar, egg yolks, cinnamon, and sometimes ground almonds.

*Other popular foods and dishes.* Flatbreads, either baked (*pão estentido*) or fried (*pão de sertã*, *torta*), stuffed eggs, stuffed eggplants, vermicelli stew, spiced meatballs, shish kebabs (*pinchos morunos*, *espetada*), and quince paste are current Iberian foods also mentioned in Arab cookbooks.

## PORTUGAL

Although smaller than the state of Indiana, Portugal was the seat of a great European empire, and its trading network has marked its culture and cuisine. Even before nationhood, Portugal was successively invaded by Celts, Phoenicians, Greeks, Romans, Visigoths, Swabians, and Moors, and was influenced by these cultures. The birth of the Portuguese nation dates back to 1139, when Afonso Henriques took the title king of Portugal, after a major

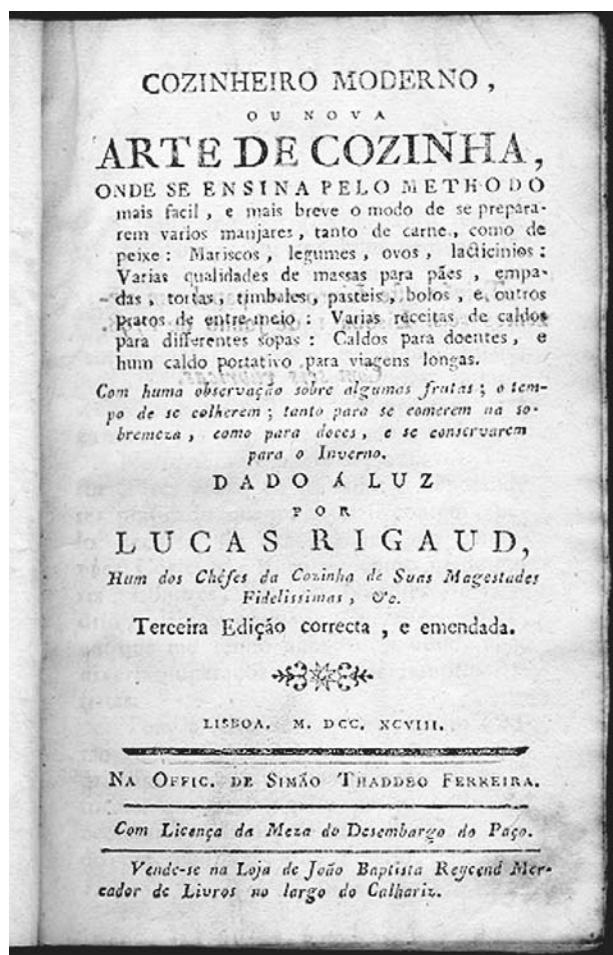

victory against the Moors, although the south remained under Moorish rule until 1250. Spain and Portugal signed the 1494 Treaty of Tordesillas, under papal auspices, dividing the New Worlds between them. The Spanish claimed the Americas, while the Portuguese acquired Brazil and the Spice Route, from Africa to Timor. Portugal's last trading colony, Macao, established in 1557, peacefully reverted to Chinese control at the end of 1999. Portuguese traders brought back to Europe a treasure of spices such as cardamom, pepper, ginger, curry, saffron, and paprika, as well as other exotic foods, such as rice and tea from Asia, coffee and long pepper from Africa, peppers, tomatoes, potatoes, tropical fruits, and peanuts from Brazil. All ingredients form part of Portuguese cuisine today. As Jean Anderson notes in *The Food of Portugal*, the ingenious combination of Old and New World foods differentiates Portuguese cooking from Spanish (p. 10).

### Regions

Portugal faces the Atlantic, whereas Spain, except for Galicia, identifies itself as Mediterranean. In the north, Minho province is a green garden of small plots and vineyards. Inland, Trás-os-Montes is a land of stark mountain ranges and hills with a severe climate. The Douro River, rising in Spain, flows to Oporto, through steep-terraced vineyards. The three Beira provinces form the Portuguese heartland, with the highest mountains. The center of the empire, Lisbon's Estremadura province received much wealth from the colonies, as is evident in its varied cuisine. The gentle plains of Ribatejo along the banks of the Tagus provide pastureland. Alentejo, meaning “beyond the Tagus,” is a vast expanse of cork oak, olive trees, and wheat fields along the Spanish border. The Moorish occupiers remained longest in southernmost Algarve, leaving their influences on the architecture, customs, and food. Portugal's only remaining overseas territories are the Atlantic archipelagos: Madeira and the Azores.

### Portuguese Eating Habits

Although young people tend to favor international fast foods, the rest of the Portuguese still prefer slow cuisine and fresh fish and vegetables. Portuguese families are increasingly dependent on hypermarkets—giant supermarkets that function like compact department stores—springing up everywhere, but the weekly farmers' markets are still very popular. Portuguese households begin the day with a continental breakfast of coffee and milk with bread and butter, honey, or jam. The main meal takes place at lunch, with an appetizer (*acepipes*) like fresh cheese or codfish balls, one course—generally meat and vegetables—and dessert. Country loaves, more refined rolls, or cornbread appear with every meal. A lighter supper can start with soup, one course of perhaps fish, and fruit. There is usually a midmorning break for coffee and a roll, and children take a midafternoon snack of sandwiches and milk. Most elegant teahouses, where ladies of

leisure used to indulge in rich egg and sugar cakes, have closed with changing work habits, but pastry shops serve the seventeenth-century convent sweets.

**Meal times.** Typically, Portuguese meal hours are closer to those of the French than the Spanish: They do not share their Iberian neighbors' midafternoon repasts and siestas or midnight suppers, except on Christmas and New Year's Eve. Lunchtime is 1:00 P.M., and many workplaces still close from 1:00 to 3:00 P.M. The traditional dinner hour is 8:00 P.M.

**Weekly cycle.** Traditional dishes like *caldeirada* (fish or shellfish stew) and *cozido á portuguesa* (boiled meat and vegetables) are served in homes on weekends to allow for more time for food preparation. Portuguese families also like to eat out on weekends. Many popular restaurants offer generous half-portions, but even so, prices have soared faster than wages, and the average family is going out less.

## Seasonal Cycle

With its temperate Gulf Stream climate, coastal Portugal does not suffer the extreme temperatures of inland Iberia. It rarely freezes, and fresh fruits and vegetables are available year round, although they vary with the seasons. Even sardines come in seasons, fatter and juicier from June through October. At year's end there is the *matança* or the killing of the pig, and the smoking of lean meat and stuffing sausages to last through the winter. Basically the Portuguese eat the same substantial meals all year. Inland, however, where summer temperatures can hover over 100°F (37°C), lighter wines are served and occasionally *gaspacho*, a cold tomato and cucumber soup, similar to its Spanish cousin *gazpacho*. There are also *escabeches*, cold marinated meats, for scalding summer days.

**Feasts and special occasions.** Religious feasts, with special foods, are still important in this Roman Catholic country. Christmas Eve supper usually features the national favorite *bacalhau cozido* or boiled dried codfish, with cabbage, potatoes, and hard-boiled eggs, smothered in garlic and olive oil. (Portuguese fishermen have been sailing to Newfoundland for cod since the fifteenth century, salting and drying it at sea. But in response to European fishing restrictions imposed in the 1990s, Portugal imports cod from Norway, which is more expensive.) On Christmas Day, the main course features roast turkey, and for dessert there is *rabanadas*, slices of bread dipped in eggs, honey, red wine, sugar, and cinnamon, and fried.

At Easter, lamb or young goat is marinated overnight in white wine, roasted, and served with baked potatoes. Lamb soup uses the lamb's heart, liver, lungs, tripe, blood, and plenty of stale bread. A popular Easter dessert is cottage cheese tarts.

Every region has a saint's festival with special foods. Lisboners pay homage to Saint Anthony with a costume parade, block parties, grilled sardines, and red wine. Oporto celebrates St. John with fireworks, street dancing, cabbage soup, and red wine. The Templar city of Tomar honors the Holy Spirit, with the Festival of Crowns, a cortege of girls, wearing tall crowns of fresh loaves of bread and paper flowers, accompanied by merrymaking and a panoply of sweets like almond cheese cakes and pumpkin tarts.

Other festive occasions include birthdays, weddings, baptisms, and first communions. These used to call for elaborate banquets, but in the early twenty-first century the menu is simpler: traditional dishes like tripe, hake filets, roast lamb, baked rice, and egg and sugar tarts.

## Regional Foods and Wines

As communications have improved in this compact country, more regional dishes have acquired national status. *Cozido á portuguesa*, the hearty Portuguese boiled dinner, with chicken, spareribs, sausages, and vegetables originates from Estremadura but is found everywhere. Other national favorites include green soup with shredded cab-

## PORT WINE

Originally port was a dry red table wine and came from the Upper Douro Valley some 2,000 years ago. Then in 1820, exceptionally warm weather produced unusually sweet grapes and the full, rich dessert wine that the English adored. To satisfy eager English customers, port wine producers added brandy, which stopped the fermentation early and preserved the high sugar level of the grapes, raising the alcohol level to about 20 percent. The process of producing port is now mechanized. The new wine is no longer transported in *rabelos*, flat-bottomed sailboats, but trucked to the port wine lodges, at Gaia across from Oporto. There it is blended and stored to mature.

The French now consume more port than the British, Pasquale Iocca of the Portuguese Trade Commission emphasizes in the *Food of Portugal* (Anderson, 2001). He points out that the British still favor vintage port ten to fifty years old, whereas the French prefer tawny port aged three to five years in casks.

bage and potatoes from the Minho, fish or shellfish stew found all along the coast, baked dried codfish (the fish is first soaked in liquid before cooking) with onions and potatoes originally from Oporto, and *açordas*, or creamy dry bread soups from Alentejo. The national sauce of crushed tomatoes, green peppers, and onions is the universal condiment. The “national” dessert is *arroz-doce*—rice pudding.

While Port and Madeira dessert wines have gained worldwide recognition, Portuguese table wines are beginning to attract more attention. There are some fifty officially demarcated wine-growing regions. The best reds come from the Alentejo, although those from Beira are better known. Increasingly popular is the effervescent white *vinho verde* or new wine, from the Minho. Excellent natural and carbonated mineral waters come from Beira and Trás-os-Montes.

**Between the Minho and Douro food culture.** Minho province, blessed by rivers, fertile farmland, trellised vineyards, and a fruitful sea, is home to an exceptionally varied cuisine. From the Minho and Lima Rivers come salmon trout and lamprey. Atlantic specialties include sardines grilled on pine needles, octopus stew, and shad vinaigrette. Pork is the dominant meat, with delicacies like pork cubes marinated in *vinho verde*.

Oporto’s unlikely favorite food is tripe. In fact, the native people are known as *tripeiros* or tripe-eaters because in the fourteenth century they donated all their

meat to feed the navy in its defense of Lisbon against Juan I of Castile. The *Portuenses* were left with the innards, which they learned to use in many innovative ways.

**Estremadura food culture.** Naturally the richest, most cosmopolitan cuisine is found in the capital, reflecting the diverse population, who settled here from all over Portugal. Lisbon’s specialties range from stuffed crab and lobster *açorda* to rice and turnip greens or codfish hash. Then there is café beefsteak, with cream sauce and french fries, which made its debut in popular cafés and is now a regular in many homes. Over the past decade, immigrants from the former colonies of Angola, Goa, and Macao

## MADEIRA

It was the visionary Prince Henry who first brought Malvasia grapes from Crete in the fifteenth century to Madeira as the basis for the island’s important wine industry. The special intense quality of Madeira wines comes mainly from the basaltic soil and mild climate. Like port, Madeira is fortified with brandy to ensure its quality during shipping, but it acquired its distinctive, slightly scorched flavor by chance. Sometime in the seventeenth century, a case of Madeira was forgotten in the hold of a ship when it reached its destination in the New World. The wine returned to Madeira considerably enriched after its lengthy sea voyage twice through the steamy tropics. Subsequently, Madeira merchants began to send their wines on long tours to enhance the sweetness and aging. Then they found they could get the same results by a process of steaming the wine at home.

Queen Catherine of Bragança, the Portuguese wife of King Charles II of England, was indirectly responsible for the popularity of Madeira wines in colonial America, according to Pasquale Iocca of the Portuguese Trade Commission. In the *Food of Portugal* he points out that because of Queen Catherine’s influence, Madeiras were the only European wines exempted from the 1665 export ban and shipped duty-free to the English colonies. The signing of the Declaration of Independence was celebrated with glasses of Madeira, and George and Martha Washington used to drink a pint of Madeira every evening with dinner.

Madeira exports virtually halted after the island’s vineyards were devastated by disease in 1852. Several English companies that were involved in producing and shipping Madeira helped to reconstitute the vineyards. By 1900, Madeiras were back better than ever, but Americans had meanwhile switched to sherry.

*Couve tronchuda* is a variety of Portuguese open-headed cabbage dating from ancient times. It is still a traditional ingredient in Portuguese cookery and serves as the main ingredient in this cabbage and sausage soup. © BECKY LUIGART-STAYNER/CORBIS.

have established new ethnic restaurants in Lisbon, which are certain to influence future eating habits.

***Alentejo food culture.*** Portugal's least developed region, the Alentejo has produced the most imaginative dishes. Frugal housewives have ingeniously used the staple ingredients bread, olive oil, and garlic to produce outstanding dishes. *Açorda á alentejana* is a creamy bread puree with coriander and poached eggs. Another dry soup is *migas*, crumbled bread and olive oil, cooked with cubes of beef, pork, and bacon. The most astonishing combination is pork and clams, with pork loin marinated in chili sauce—the flavors meld together beautifully.

***Food culture of Madeira and the Azores.*** In 1425, Portuguese navigators discovered uninhabited, forested islands, some 350 miles off the Moroccan coast, which they called Madeira (wood in Portuguese). Realizing the islands' importance as a stopover for transatlantic shipping, Prince Henry, in the fifteenth century, sent over settlers, mostly from the Minho, to plant sugar cane and vineyards. Despite the distance, Madeira's cuisine is very Portuguese, enhanced with other influences. Fresh tuna steaks and scabbard fish are marinated in garlic and olive oil and fried, but served with fried cornmeal and even corn-on-the-cob. The local *cozido* includes the usual pork and vegetables, but also sweet potatoes, green pumpkin,

and couscous. Madeira's fruit salad, however, is strictly local and includes papaya and passion fruit.

The nine Azores have the closest ties to the United States. In the old days, whaling crews from the Azores sailed to New England and California, many settling there with their families, who still visit the islands in summertime. Commercial whaling has stopped, but many Açoreanos live by fishing, and fish is an important part of the diet. Fish soup Azores style includes the local catch: haddock, porgy, grouper, mackerel, swordfish, eel, and squid or octopus. Dairy farming and cheese making are also important activities, and the fragrant, moist cheese from São Jorge Island is a bestseller on the mainland.

***Food culture of other regions.*** In the wild, hilly Trás-os-Montes, the pig is "king" and fed with table scraps. In the past, the prevalence of pork caused problems for the many Jewish converts. Maria de Lourdes Modesto recounts in *Traditional Portuguese Cooking* how the "new Christians" invented *alheiras*, a delicious, porkless sausage based on partridge, to escape detection by the Inquisition's spies (p. 47). *Alheiras* are still popular, but sometimes include pork.

Mountain folk of Upper Beira are masters with leftovers. After roasting a baby goat that is basted with white wine, the head is boiled for broth, the backbone and the

## FURNAS

One of the most traditional dishes of the Azores is *cozido de lagoa das furnas* (boiled dinner from Furnas Lake). This lake on São Miguel Island is a volcanic crater, and the beach contains numerous *caldeiras* or small caverns spewing sulfur. Chunks of beef, pork, and chicken, sausages, bacon, turnips, carrots, potatoes, and red peppers, covered with cabbage leaves, are put into an aluminum pan, with the lid tightly shut. The pan is placed in a cloth bag, with a long string, and let down into a *caldeira*, then covered with a wood board and volcanic sand. The *cozido* takes about five hours to cook in the steaming ground—the ultimate in Slow Food.

heart, liver, and lungs stewed, and the cutlets are fried and always served with boiled potatoes. Beira also produces Portugal's creamiest cheese, made from long-horned sheep that feed on wild herbs in a demarcated zone of the Estrela Mountains.

The Ribatejo, with its alluvial plains, is famous for its dark full-bodied red wines and substantive dishes like stone soup made from pig's ear, *chouriço* (a spicy sausage), ham, and red kidney beans.

Algarve's clean beaches, sun, mild sea, and air temperatures have made it Portugal's primary tourist resort, and this situation has threatened it with a loss of identity. By avoiding international establishments, it is still possible to find original Algarve seafood dishes, like octopus with rice, tuna steaks in onion sauce, or squid stuffed with ham and *chouriço*.

## SPAIN

Spain, situated on the westernmost peninsula of Europe and opening to the Atlantic Ocean on the northwest, historically has been oriented toward the Mediterranean both in its climate and in the temperament of its people. First settled by Celts, then invaded by Phoenicians, Greeks, and finally the Romans, who consolidated the peninsula into one province, ancient Spain became one of the most important agricultural regions of the Roman Empire. Following the Romans came the Goths, then Nordic invaders, and finally the Arabs, so that during the Middle Ages the country fragmented into many small kingdoms. Those former kingdoms roughly correspond to the provinces and regional cultures comprising modern Spain. Each of the invading peoples added its own identity to the rich mixture known as Spanish cuisine.

### The Main Cultural Regions

Galicia, which has Celtic roots, is in the far northwest of Spain, and to the east are Asturias and the Basque country, whose culture and language predate Roman Spain. To the east of Asturias are Navarre and Catalonia, two important kingdoms during the Middle Ages that established Spain as a major maritime power in the Mediterranean. Along the western border with Portugal is Extremadura, and in the Spanish heartland to the east are Old and New Castile. Along the Mediterranean coast in the South, opposite Africa, are Andalusia and the Comunidades of Valencia and Murcia, all with distinctive regional cookeries and internationally known wines. The Arabic influence was strong in these regions and lingered in many aspects of the culture, perhaps best typified by the great Moorish palace of the Alhambra in Granada. Of course many islands are part of Spain, among them the Balearic Islands of Minorca, Majorca, and Ibiza and the Canary Islands off the Atlantic coast of Africa. No matter how Spanish culture is studied, it is obvious that this huge diversity rather than any one element of it defines the cuisine of modern Spain.

Added to this diversity is the climate. In the northern coastal area the weather is generally cool, even rainy, whereas in the central and southern parts of the country the climate is hot and dry like other parts of the Mediterranean. Thus even in its kitchen gardens and agriculture, the country exhibits a great diversity. In addition several gastronomic riches of the New World, including the tomato, the potato, the capsicum pepper, cacao, and vanilla, reached Europe via the Spanish Empire.

### The Characteristics of Spanish Eating Habits

Not until the late twentieth century did a "national" Spanish characteristic for the times and places of food

Traditional olive oil storage jar. Spain, seventeenth century. Gray earthenware. The design is based on the ancient Roman *dolium*. The exterior of the jar was sealed with pitch (still extant), then sunken into the floor of the cellar. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

consumption emerge. Previously the family determined such patterns locally, but new family structures and work customs shifted the patterns dramatically. The typical pattern became two main meals (midday dinner and supper), a light breakfast, and two optional meals (tapas and *merienda*). Breakfast, the first meal, generally corresponds to the European continental breakfast, consisting of a quickly eaten, fortifying menu based on pastries, small breads, coffee, milk, butter, and marmalade, and it is essentially of French origin. Alternatively something totally Spanish, such as *churros* and *porras* (fritters) can be substituted.

**Main meals.** The most typical feature of the meal schedule is the tendency for Spaniards to delay the timing as much as possible. When midday dinner is adjusted to the work schedule, it usually takes place at around 2:00 P.M. On the other hand, when festivities or vacations allow more flexibility, Spaniards tend to postpone it until 4:00 in the afternoon for relaxation or friendly reunions or because of the earlier consumption of tapas. The most significant feature of the Spanish midday dinner is to prolong it as late into the day as possible with the help of desserts, liqueurs, and coffee. Its only rival activity is the siesta or midday nap. This dinner involves a major consumption of food. After the Spanish Civil War (1936–

1939) families began to eat at the table three main dishes plus appetizers, cheeses, and dessert. Subsequently this pattern devolved into two main dishes and dessert.

The traditional Spanish supper usually takes place around 10:00 P.M., also in the home. It is characterized by its pretension of being light, although it consists again of two main dishes and dessert. Vegetables and fish are often preferred to assure that it is less heavy than the midday meal.

**Meals between meals.** Spaniards, being of a relaxed, Mediterranean temperament, have created a minimeal between breakfast and midday dinner. This meal, called an appetizer elsewhere in the world, is referred to in Spain by the verb *tapeo* (to eat tapas). Drinks and food are of equal importance to eating tapas. It is also popular among Spaniards to not eat the tapas in one establishment but rather to stroll through various eateries throughout the course of the morning.

A classical tapa can be eaten with a toothpick, in small pots or bowls with a fork, or on top of a piece of bread. All of these variations have their own descriptive nomenclatures based on appearance: *pinchos*, *cazuelitas*, and *montados*. Drinks of low alcoholic content, such as beer and wine, are always drunk with the tapas. In the South wines such as Jerez, Fino, and Mazanilla are served. Usually the higher the alcoholic content of the beverage served, the smaller the quantity of food consumed until, at the far extreme, tapas simply become dried fruits and olives.

**Merienda.** *Merienda* is the meal between the midday meal and supper. Generally it is a meal for socializing during afternoon visits or during a game of cards, or for children and the elderly who require extra nourishment between fixed meals. The drink most representative of the Spanish *merienda* is chocolate. Spanish-style chocolate is characterized by its thickness, although it is traditional to drink it in small cups called *jícaras* accompanied by absorbent cookies that can be dipped into the chocolate.

Another *merienda*, easy to eat during journeys, is the *bocadillo*. This is the equivalent of the sandwich, but it is prepared with a whole loaf of Spanish bread. During times of food shortages, *bocadillos* have been filled with sliced quince or a little grated chocolate. The more classical *bocadillos* are made of *serrano* ham and *manchego* cheese.

The *bocadillo* has undergone a gradual evolution. It is used as a quick meal suitable for any hour of the day since all of the basic types of nutrients can be put into the loaf, such as chorizo (a spicy pork sausage), *calamares a la romana* (squid fried in butter), sardines, or *tortilla a la española* (Spanish omelet). For excursions to the countryside something special is created, *bocadillo* filled with breaded filet of beef.

**The weekly meal cycle.** The Spanish housewife generally makes a clear distinction between the everyday meal

and the festive meal, especially on Sundays. Traditionally it was possible for working husbands and schoolchildren to eat in their own homes every day, and only manual laborers were obliged to eat at work. Housewives created a varied menu by distributing dishes representative of each day of the week—for example, Monday macaroni, Tuesday lentils, Wednesday stew, Thursday broiled fish, Friday porridge, Saturday salads, and Sunday paella. Depending on the economic means of the family, beef could be a choice, especially for Sundays. This custom continues in the “dish of the day” on restaurant menus.

### The Seasonal Cycle

In spite of the geographical diversity of Spain, a shared seasonal climatic variation is common to all parts of the country. Thus, except for the colder regions, summer tends to be hot throughout Spain, which defines the character of summer meals. The foods of the warm season favor easy preparation and light, refreshing ingredients, such as salads and gazpachos. The basic ingredients of a typical salad are lettuce and tomatoes, and the simple salad dressing—olive oil, wine vinegar, and salt—is prepared at the beginning of the meal by the guests themselves. This custom has continued in public restaurants. When the server places the cruet stand on the table, it is a sign that one of the dishes will include lettuce.

The “king” of all the first course dishes is gazpacho, one of the great contributions of Spanish cooking to hot weather cuisine. It is similar to a cold tomato soup, but in gazpacho all the ingredients, ripe tomatoes, cucumbers, green sweet peppers, garlic, olive oil, salt, and vinegar, are raw and are liquefied. Cold water is added to thin the soup. At restaurants it is served with garnishes, consisting of the same ingredients cut into small pieces, and small bits of bread.

In Spain the cold season is associated with the consumption of legumes. Lentils are part of a tasty repertoire of everyday meals, but when Spaniards want to feel satisfied, they think of garbanzo stew. When they want to feel extremely full, they think of the *fabada asturiana*. The *fabada* is a thick stew of white beans and pork products from the region of Asturias on the coast of northern Spain.

### The Festive Cycle

The celebrations that have influenced Spanish gastronomy the most are the religious feasts, notably Christmas, a time when major excess prevails. The traditional feast days are Christmas Eve dinner on 24 December, Christmas Day dinner on 25 December, New Year's supper on 1 January, Three Kings supper (Epiphany Eve) on 5 January, Epiphany breakfast on 6 January, and Epiphany dinner on 6 January.

During the Middle Ages, Christmas Eve dinner followed a vigil, and from this period a light dish called *sopa*

*de almendras* (almond soup) survived as a nostalgic relic. Only after midnight mass, or *misa de gallo*, could the great gastronomic excesses begin. Eventually this became the preeminent family dinner. The traditional dishes have continued, although they have evolved over time. Earlier the meal consisted of savoy or red cabbage and fish, usually red porgy, but grilled leg of lamb has become the porgy's competitor.

Certain Spanish confections, such as *turrónes*, *marzapán*, and *polvorones*, convey a nostalgic dimension to Christmas, since they are only consumed at this time. The Christmas meal is family oriented, and turkey is the main dish. New Year's festivities tend to lose their family orientation, since New Year's Eve is a supper prelude to a party outside the home. Consequently it is light and easy to prepare, generally a cold meal of various seafoods, especially prawns. The cheapest and most common prawns are baptized with plenty of Catalan Cava (Spanish champagne).

Three Kings' supper on Epiphany Eve is a magical night for children, since they wait for gifts from the Three Kings of the East. The breakfast on Epiphany morning would not be of major importance were it not for the fact that the Magi have brought a *roscón*, a large, round, braided bread flavored with orange-flower water and decorated with crystal sugar, chopped almonds, and dried fruits. Spaniards give each other *roscones de Reyes* until every house has a great accumulation of them.

Lent is a period of recovery, forty days of penitence preceding the celebrations of the death and resurrection of Jesus. The traditional vigils and fasts during these forty days have developed many variations over time, yet the vigil dishes and the dishes of nourishment for days of fasting are a form of nostalgia or remembrance. The representative dish of a vigil is a *potaje* consisting mainly of garbanzos, dried codfish, spinach or cabbage, hard-boiled eggs, and a touch of cumin. During Lenten fasting one characteristic sweet, called *torrija*, is consumed. It is made with sliced bread soaked in milk and sugar, dipped in an egg batter, fried in olive oil, and drowned in wine, orange juice, or honey.

In addition to these great religious observances, each region of Spain has its own patron saint, who is celebrated with some characteristic meal. The confections made in the saint's honor add a special note to the extraordinary fare of the celebration and have given rise to numerous types of *rosquillas*, *panecillos*, and *bollos* ornamented with saintly symbols. Remarkably bakers invent new recipes for modern festivities, so many traditional observances are revitalized on a daily basis.

### The Regional Cookeries of Spain

Because Spain has varied regional identities and diverse agricultural districts, regional cooking has acquired a special meaning. Besides the different languages and dialects, regionalism is thoroughly manifested in highly varied

gastronomic traditions. In spite of this localization, many dishes have become popular over the entire country.

Local inns and taverns have a commercial interest in exposing consumers to dishes representative of the region. These can be identified by their last names, such as *a la gallega*, *a la asturiana*, *a la riojana*, *a la catalana*, *a la valenciana*, *a la murciana*, *a la andaluza*, just to mention a few specialties. Obviously these dishes are not always accurately prepared outside their regional settings, but they do allude to distinct culinary styles. Each regional capital has centers, called Casas Regionales, representing the cultures of other regions. These centers normally include restaurants that serve food typical of the regions they represent. All of Spain's regional cookeries are accompanied by an enormous diversity of wines that gradually have become certified by their nominations of origin, including sparkling Catalans, red Riojanos with a *ribera del Duero* body, and full-flavored Andalusians, plus a series of local liqueurs, the outstanding one being Anis.

**Basque cookery.** The importance of Basque cookery rests on the great Basque love for gastronomy and on the high quality of the natural products from that region, of which fish is the most important. In Basque country the clubs called Sociedad Gastronomica are exclusively for men. Whatever food they prepare themselves, they must also eat. The purpose of this society is to conserve traditional Basque cookery, but the members also are mindful of creative new cooking techniques. Out of this region great chefs, including those from the Basque part of France, given its close proximity, have emerged with innovative talents. In any city of Spain a restaurant run by a Basque chef will be well known for the high quality of its cookery.

Of the fish caught along the Basque coasts, the most notable is hake, which is also one of the most expensive. However, its closest relative, weakfish, is generally less expensive and equally tasteful. The best dark-fleshed fish also come from these waters, such as bonito and tuna. Basque sardines and anchovies have earned international popularity, and an industry has developed around preserving sardines and salted anchovies in oil.

Among the dishes most representative of Basque cookery, hake in green sauce stands out, as does *marmittako*, a stew composed of chopped bonito and potatoes with olive oil. The Basque secret of preparing codfish *al pil-pil* is the peculiar pan-shaking movement that must occur at the correct moment of cooking to emulsify the sauce. The typical wine from this region is *txacolí*, a young wine of low alcoholic content.

**Castilian cookery.** The central part of Spain is an extensive region known historically as the two Castiles. It is an area characterized by plateaus and a continental climate, cold winters and hot, dry summers. The area is rich in cereal products and herds of wool-producing animals, both sheep and goats. During the cold season residents

consume legumes, most commonly garbanzos and lentils. Castilian-style garbanzos have given their name to the famous dish *el cocido madrileño*. Grain products hold an important place among the region's numerous shepherds, who make a light meal—by frying flour or pieces of bread in olive oil, garlic, ground red pepper, and bacon—called *migas de pastor*.

From Castile comes the best quality Spanish lamb, which when grilled attains a level of specialty by virtue of its utter simplicity. This area of Spain is also famous for its traditional method of grilling lamb and suckling pig. The cold, dry winters are traditionally the time for pork butchering, resulting in the famous chorizo sausage. This region also produces the famous *manchego* sheep's milk cheese, which gets its aromatic flavor from the wild herbs growing in the pastures where the sheep graze.

**The cookery of Valencia.** This style of Spanish cookery is famous for its clever use of rice. It has been said that the region's cooks are capable of producing 365 rice recipes, one for each day of the year. The two most famous rice recipes from this region are *paella valenciana* and *paella alicantina*.

Spanish rice is cooked with a precise proportion of grain to water so, at the end of the cooking process, the grains are perfectly fluffy, with no stickiness from excess water. The *bomba* variety of rice is ideal for paella, since it absorbs the stock surrounding it, producing the best texture.

The classic *paella valenciana* is composed of elements from the kitchen garden, chicken, rabbit, vegetables, and snails. *Paella alicantina* is essentially composed of seafood. It is visually attractive, presented at the table with shellfish, lobsters, shrimp, and prawns arranged radiating from the center. In both types of *paella*, saffron is essential to give the rice a yellow color and a distinctive flavor.

**Andalusian cookery.** Andalusia is one of the world's major producers of olive oil, and it has a bountiful sea-coast and hot Mediterranean weather. These characteristics have given the regional cuisine its primary features, the refreshing gazpachos, the fried fish, and a style of cookery generally easy to prepare and accompanied by richly flavored wines. Andalusian fish fries are especially famous, and the best cured ham comes from this region.

The high quality of the region's ham is due to the fact that the *cerdo ibérico* (Iberian pig) breed is raised mostly in this region. The pigs' special diet in the pasture and a unique curing process contribute to the fine flavor of these hams, which are classified as *serrano* (plain cured) and *bellota* (acorn ham). *Bellota* comes from Iberian pigs fed on acorns, which achieves a flavor somewhat on the sweet side. This ham is of such prestige that it has been called Spanish "caviar."

**Other regions.** In addition to the culinary regions already mentioned, Galicia includes the best seafood, Ri-

## PAELLA VALENCIANA

The paella is the pan used to cook this legendary dish, and valenciana refers to Valencia, the region of Spain on the shores of the Mediterranean where it originated. It is typically cooked outdoors in the countryside on a dry wood fire. The paella must be set at a suitable height to be surrounded by the flames during the first part of the cooking, and the fire must be kept burning at the correct strength.

Generally a good paella depends not so much on the quality of the ingredients as on combining all the components in the correct proportions. The five basic elements—oil, water, rice, heat, and cooking receptacle—need to be balanced with an almost mathematical precision. The experience and personal touch of whoever is in charge of the cooking are also of utmost importance.

The preparation of a paella in the countryside is a ritualistic festive occasion, which can sometimes turn into a gastronomic debate! The relaxed, lighthearted atmosphere is punctuated with jokes and comments on the progress of the food.

The experience culminates when the paella is deemed ready, removed from the fire, and carried to the table.

### Ingredients:

- 6½ oz. (200 gr) fresh or dried large lima (butter) beans, or *fava* (broad) beans, soaked overnight
- 4½ cups (2 qt. / 2 l) water
- ⅔ cup (5 fl. oz. / 155 ml) olive oil
- 1½ lb. (750 gr) chicken, in chunks

- 1 lb. (500 gr) rabbit or lean pork, in chunks
- 8 oz. (250 gr) green beans, trimmed and halved
- 1 tomato (3½ oz. / 100 gr) peeled and finely chopped
- 1 teaspoon paprika
- salt
- 12 small land snails or 1 sprig rosemary
- 2 pinches saffron
- 2½ cups (13 oz. / 410 gr) medium grain rice.

Put the lima beans on to boil in 2 cups (16 fl oz. / 500 ml) of water.

Heat the oil in an 18-in. (45-cm) paella (shallow metal pan) and fry the chicken and rabbit chunks, turning to ensure even cooking. Add the green beans and fry gently. Keeping the heat low, add the tomato, then the paprika, immediately followed by the rest of the water.

Add the lima beans with the cooking water. Add salt and bring quickly to a boil, then turn down the heat and continue cooking until the meat is cooked (45–60 minutes).

Add the snails or rosemary. Check the seasoning and add the saffron. Turn up the heat and add the rice, spreading it out as evenly as possible. Cook quickly for the first 10 minutes then turn down the heat gradually for another 8–10 minutes.

Taste the rice to check if it is done. The grains should be soft but still quite firm inside. Remove from the heat and allow to rest 5 minutes before serving. Serves 4.

*Lourdes March*

oja produces the highest quality Spanish wines, Catalan cookery is notable, and many subregions are incorporated within the larger provinces. The cookery of Galicia in particular benefits from the rugged coastline, ideal for nurturing quality seafood. Furthermore, its inland prairies produce beef and veal famous throughout the country. The delicious empanadas of medieval origin are made with the products of both land and sea.

The cookeries of Navarre and of the Rioja region enjoy the benefit of being in areas with special microclimates, and they are privileged with many bays and river valleys, where rich soils produce appealing vegetables. These vegetables are the ingredients in excellent stews that have encouraged mammoth feasts.

Catalan cooks, in their desires to rescue local traditions and to blend them with an innovative curiosity, compete with the Basques for first place in the Spanish

kitchen. Their emphasis on grills and wood-burning fires is most likely of Roman heritage. As in Roman times clay tiles are used in cooking mushrooms, vegetables, fish, and meats. Catalan sauces or *picadas* are made by pounding mixtures of aromatic ingredients, such as garlic, dried fruits, tomatoes, herbs, olive oil, salt, and even cookies to give them a surprisingly sweet flavor. The weight of tradition is also reflected in Catalonia's varied ornamental confectionery.

Other regional foods, of no less importance, include the Murcian, with its fish chowders and the cookery of the Balearic archipelago, probably the most ancient style of cooking in Spain. Extremadura on the Portuguese border and the Canary Islands possess culinary riches inherited from Spain's age of discovery. From their cities came the curious voyagers who inaugurated Spain's expansion into a world empire, the true beginning of globalization.

**ICE CREAM.** Ice cream, or iced cream as it was originally called, was once narrowly defined as a luxury dessert made of cream, sugar, and sometimes fruit congealed over ice. The techniques for making water ices and sorbets probably led to experimentation with cream and milk in Italy during the Renaissance although no recipes survive. On the other hand, there is clear literary evidence that this experimentation underwent considerable refinement in France during the seventeenth century, and that it was the French court of Louis XIV that first served ice creams at banquets. The use of snow and ice to cool wines was known to the Romans, and sorbets were well known to the Persians and Byzantine Greeks. It does not take a large leap in technology to go from sorbets to frozen creams, yet it was the use of sweet cream from cow's milk that originally made true ice cream possible. In fact, it is the rich milk from certain breeds of cattle that further defines the texture and flavor of this product.

### Early Techniques

The original technique for making ice cream was relatively simple, although it was predicated on a good supply of ice or well-packed snow. A large pewter basin was filled with coarsely broken ice, over which the confectioner scattered salt. Salt lowers the melting temperature of the ice and thus induces evaporation. Another smaller pewter basin was set into the salted ice. This basin contained the cream, sugar (usually in the form of syrup), and flavoring—lemon being by far the most popular ice cream flavor until the 1850s. The small basin was then turned by hand and the cream mixture stirred gently until it congealed due to the cooling action of evaporation. Otherwise, it was still-frozen, then beaten once firm. This method is found in numerous recipes surviving from the latter half of the sixteenth century, as well as in quite a few eighteenth-century printed cookbooks, including the *Receipts of Mary Eales* and Hannah Glasse's *Compleat Confectioner*.

The cookbook of Mary Eales, which appeared in 1718, is considered the first to feature an ice cream recipe printed in English, and it varies in technique from the basin method just described. Eales placed her cream in pails in an ice chest and still-froze them, a method developed by professional French confectioners and similar in shape to the crank-turned freezers of the nineteenth century. The appearance of ice cream in domestic cook-

books of the period may be taken as evidence that ice cream had moved from strictly palace fare of earlier times to the tables of the literate well-to-do. This is confirmed in America by a 1744 reference to ice cream on the dessert table of Governor Blandon of Maryland—a thing to be marveled at and noted diligently in a dinner guest's diary. The governor's ice cream was served with fresh strawberries, a foreshadowing of the ubiquitous strawberry and ice cream festivals that today have become such an integral part of the American cultural scene. As for Governor Blandon, it goes without saying that many wealthy colonial Americans owned icehouses, which made such luxuries possible.

Implicit in the operation of making ice cream was the use of metal that transfers the cold temperature of the ice as quickly as possible to the cream. Pewter was the preferred metal of most ice cream makers down to the end of the nineteenth century, when it was replaced by other alloys. The reasons for replacing pewter were several: it pitted easily and it was soft. Complex molds made of pewter would eventually warp or bend, especially around the area of the hinges, which would lead to leaks and imperfectly shaped molded ices. Most important, pewter reacted chemically with acids in ice creams, thus forming toxic lead salts. This realization did not occur to confectioners until the chemistry of food became better understood; thus, it is highly probable that toxins in ice cream contributed to some of the maladies suffered by consumers in the past. This was certainly the case prior to pasteurization because freezing cream or milk does not kill microbes or prevent enzyme breakdown. However, none of these modern concerns affected the historical popularity of ice cream in Europe or America. It would probably be more accurate to say that ice cream became such a rage that its negative effects on the body were rarely mentioned even in medical literature. The loudest critics of ice cream bemoaned the costliness, for ice cream was indeed an expensive indulgence until the invention of the commercial ice cream maker in the late 1840s.

If French confectioners brought ice cream to the attention of the world by serving it at the French court, these same confectioners also codified the art of making ice cream so that, by the middle of the eighteenth century, numerous books could be consulted on ice cream making from A to Z. While the basin method was generally a technique employed in household confectionery, professionals made ice creams in ice chests and experimented with various substances to enhance freezing, including alum and saltpeter. The French also coined the term *fromage glacé* for true iced cream and introduced such unusual flavorings as cinnamon, chocolate, bergamot, and orange flower petals. The French in addition developed the concept of serving ice cream in tiny glasses, normally arranged on glass salvers. These standing displays, sometimes stacked very high, are depicted in quite a few confectionery books and necessitated the invention of tiny pointed spoons for eating the creams.

As ice creams became more fashionable, the formulas for making them also became more and more complex. This was especially true for ice creams that were molded because they required a firmer body than the old hand-whipped sorts. Cutting cream with milk and the addition of eggs, all of which was gently cooked until thick, became one of the signature methods used by French confectioners. Modern American ice cream producers generally call such cooked egg-thickened ice creams “French,” as in French vanilla ice cream, although in the nineteenth century Sarah Rorer in Philadelphia and Agnes Marshall in London categorized them emphatically as Neapolitan. In fact, cooking the milk or cream was practiced by more than just French confectioners, and in America at least it was associated primarily with Italians. Neapolitan ice cream was also a specific flavor combination: three distinct layers, one green (pistachio), one white (vanilla), and one orange (orange flavor) in imitation when sliced of the Italian national flag.

### The Popularity of Ice Cream

The French Revolution did much to spread the popularity of ice cream, especially in England and America, where refugee confectioners set up business. Some of the most active French confectioners settled in New York and Philadelphia, and their advertisements for ice creams are common in American newspapers from the 1790s into the 1820s. It was also during this period that ice cream gardens developed. They featured a confectionery shop where a variety of sweet foods were prepared, where wines and lemonades were served, and even elaborately planted flower gardens and, on occasion, musical entertainment. Since the best cream was seasonal—May and June being the optimal months—the ice cream gardens also offered cooked food to such an extent that many of them resembled outdoor restaurants. The cookery, however, was light, and for the most part appealed to women and children, since they could not enter oyster houses or taverns unless accompanied by a male. Ice cream gardens became safe havens where even teenage girls could socialize (or flirt) with budding admirers. Furthermore, ice cream gardens were off-limits to African Americans; thus in cities like Philadelphia, a number of black cooks established their own counterparts. Once commercial ice cream became less expensive, the ice cream garden was replicated by churches as a fundraising event under the name of an ice cream social.

The most famous ice cream in nineteenth-century America came from Philadelphia owing to the proximity of fine dairies, rich pasturage on which to feed the cows, and no small amount of local ingenuity. While several French confectioners established a penchant for rich ice creams during the 1790s, especially the demand for finely molded *fromages glacés* at supper parties and balls, it was the Parkinson family who put Philadelphia ice cream on the map.

George Parkinson and his wife Eleanor created a confectionery business that made Philadelphia vanilla ice

Puss-in-boots ice cream mold. New York, circa 1881. Pewter alloy (cleaned). Like period gingerbread molds, themes for ice cream molds were derived from popular culture. In this case, the mold design is based on an 1881 Christmas trade card (next page). ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

cream a synonym for the city's haute cuisine. Their son James opened a restaurant in the early 1840s with an ice cream garden in the back—situated in the center of an elaborately pruned collection of roses. Parkinson's sales bills, advertisements, and surviving menus offer a rich selection of ice creams and ice cream sculptures. When Swedish singer Jenny Lind visited Philadelphia in 1850, Parkinson sent to her hotel room an ice cream harp complete with an ice cream nightingale perched on top (the singer was nicknamed the “Swedish Nightingale,” hence the allusion). The ice cream was served on a huge silver platter together with a Bohemian glass ice cream service, molded jellies, and “iris-colored” cakes. Parkinson's showmanship did not go unrewarded. The story of the ice cream and Lind's response made national headlines. Parkinson's ice cream flamboyances and another important local development in the history of ice cream probably worked together to establish this food as a national dish. Ice cream is certainly viewed today as an American food, but its transformation would never have happened without Eber C. Seaman.

### The Impact of the Crank-Turned Ice Cream Machine

Seaman was a New Jersey Quaker who invented a crank-turned ice cream machine, which he patented in 1848. His invention was first tested in the ice cream saloon of Mrs. E. A. Harbach, a Philadelphia confectioner also famous for her candies. Until the invention of Seaman's device, ice cream had to be made in small batches by

Chromolithograph folding trade card issued for Christmas 1881 by the Philadelphia dry goods store Sharpless & Sons. ROUGHWOOD COLLECTION.

hand. Seaman's crank-turned machine allowed one person to turn out many large batches of ice cream in a matter of hours. This brought down the unit cost of ice cream so that, within a short period of time, it became little more than a street commodity. Seaman's invention is what allowed the American love affair with ice cream to blossom. His large commercial machine was soon miniaturized so that anyone with a supply of ice could make their own ice cream by the quart or gallon. Thus, the hand-turned ice cream machine became a common household utensil by the 1880s, and numerous pamphlet-sized cookbooks were sold to go with them, all including detailed directions for ice cream recipes. One of the most popular brands of ice cream machine was the White

Mountain, which gained many testimonials from leading cooks of the day.

Sarah Tyson Rorer of Philadelphia was a champion of such ice cream pamphleteering, primarily in her role of product endorsement. Rorer's New England counterpart was Mary J. Lincoln of the Boston Cooking School, whose magazines are today a gold mine of period ice cream recipes and illustrations, especially of the odd ways in which the creams were styled for presentation. One wonders whether her ice cream in the shape of a beef tongue realistically colored would have appealed to all sensibilities. On the other side of the Atlantic, Agnes B. Marshall of London not only offered her own patented ice cream freezer, a rich selection of elaborate ice cream molds, but also Marshall's patent ice cave for transporting ice creams to picnics, and two technical books on the subject: *The Book of Ices* (1894) and *Fancy Ices* (1922). Her domination of the late Victorian world of ice cream outshines the likes of either Rorer or Lincoln, and her cookery books are now considered classics of their genre. While Marshall is now part of history, her popularization of iced soufflés and especially of iced puddings has been long-lasting, especially in British cookery.

The future of ice cream, however, was not prophesized in the books of Marshall, but by Rorer. She broke down ice creams into these pragmatic categories: Philadelphia ice cream (using cream only), Neapolitan ice creams (frozen custards employing eggs), and ice creams from condensed milk or a product called evaporated cream. She also included in her 1913 cookbook a recipe for an "Alaska Bake" that was ice cream baked under a thick coating of meringue. In the last two examples, she was somewhat forward-looking in that baked Alaska became popular by the 1920s, and the shift away from natural ingredients to all sorts of artificial additives was already beginning to overtake commercial ice cream production in the early 1900s.

The first step in this evolution was the introduction of condensed milk by Gail Borden in 1856. Commercial thickeners appeared during the 1870s in the form of powders, such as powdered egg yolks, then various gelatin products, both animal- and plant-based. Finally, in 1899 the French introduced homogenizers that largely served as cream substitutes. This led to ice cream powders.

### Espoused Health Benefits

Home ice cream making was always fraught with uncertainties, especially the achievement of good texture. Ice cream powder was introduced as a fail-safe remedy with health benefits thrown in for good measure. As one 1908 Jell-O cookbook claimed, "the healthfulness of good ice cream is beyond question. In many cases of illness the patients crave ice cream, and doctors and nurses tell us that it is usually good for them." This reasoning harks back to the Italian sorbets of the eighteenth century, which were often administered to patients suffering from high temperature. But those ices were primarily water

and sweetened fruit juice, which the body metabolizes differently from dairy-based products.

The health slant was doubtless an attempt to adjust to the Pure Foods Act of 1906 because this same point is echoed across the board in most confectionery advertising of the period. After the United States acquired Cuba, the per capita consumption of sugar soared. Sugar began to permeate all aspects of the American diet, and this trend has not stopped. Yet, as an antidote to demon rum, the fountains of sugar at the ice cream parlor ("parlor" denotes respectability) or local drugstore became the morally correct culinary altar for Methodists, Baptists, and other dry denominations. It was in that blue law mi-

lieu that the ice cream sundae was born at Two Rivers, Michigan, in 1881. The sundae transformed plain ice cream into a rapture of chocolate syrup, chopped nuts, and candy tidbits known as nonpareils.

#### Ice Cream as a Part of Street Culture

Meanwhile, in cities where large communities of Italians settled, the hokey-pokey man became a fixture of popular street culture. He was an ice cream vendor and moving sandwich stand par excellence, with a small pushcart and a variety of Neapolitan flavors—Naples being the presumed origin of all the ice creamers in that line of work. The hokey-pokey man sold ice creams in paper

cups and in paper cones so that customers could walk and eat at the same time. They also sold ice cream called penny licks. These were little glasses that contained a penny's worth of ice cream, a marketing gimmick aimed primarily at children. When the ice cream was eaten, the glass was given back to the vendor, who then washed it and refilled it for the next customer. The hokey-pokey man gave rise to a flavor of ice cream in cities like New York and London. In Philadelphia, his name attached itself to a hokey sandwich made with an antipasto salad of cold meats and lettuce now known as the hoagie.

### The Ice-Cream Cone

The inventor of the ice-cream cone is not known, although claims abound. There is ample evidence that the concept existed in several forms long before the debut of the cone at the St. Louis World's Fair in 1904. The benefit of the cone was that the ice cream container could be eaten, yet if one is to accept the research of Brian Butko (2001), there was considerable resistance to the idea when it first attracted public attention. Hygiene was one reason, sticky fingers another. The public perception of ice cream was that it should be clean, like milk itself, a food that was both basic and culturally defining. The ice cream parlor and the drugstore soda fountain probably did more to help the ice cream cone gain acceptability in the long run, but it was the carefully wrapped ice cream snacks of the 1920s that eventually captured the market.

That ice cream should assume its hallowed place beside the drug counter during Prohibition may seem at first glance the most remarkable of fates, but it was the original idea that ice cream was both safe and healthy that allowed it to invade the domain of the local apothecary. Temperance instilled Americans with a love of drugs as a substitute for luxury: patent medicines were mostly alcohol, and the tempering qualities of ice cream were not known to cause a Fourth of July picnic to degenerate into debauchery. Perhaps this is one reason why American ice cream evolved into yet another branch of frozen snacks during the 1920s. Perhaps it was also due to a shift in lifestyles and altruistic spin-offs geared toward Hollywood and a need to provide movie theaters with frozen finger foods. Whatever the reason, one of the most important additions to the ice cream story arrived in the form of ice cream "novelties," to use a term then current.

### Ice Cream Novelties

This included such portable snack foods as the ice-cream sandwich, the popsicle, and the Klondike, which is today the most popular of all ice cream products of this type. Most of these foods were born about the same time. Eskimo Pies were first marketed in 1921. Good Humor's ice cream "suckers" initially appeared in Youngstown, Ohio, in 1922. And in response to the success of Eskimo Pies, Isaly's of Pittsburgh created the Klondike, its polar bear logo curiously similar to the polar bear used by Mar-

shall in her famous book of ices. Isaly's went on to become a household name in the Midwest, and their popular skyscraper cones left no doubt that even ice cream could assume phallic meanings.

### Ice Cream in the Twenty-First Century

Ice cream has now come full circle. Most of it is extremely cheap and for this reason it has lost its sexiness. Low-fat dieticians have decried it as the frozen grease that clogs our veins. Ice cream has become for many the moral opposite of granola or a raw carrot. However, people gorge on ice cream that they feel is safer, which has not only lost its cream, but instead is made entirely of nondairy products, euphemisms for ingredients that never passed through a cow. It might be far more healthful to eat real ice cream in moderation and enjoy a long walk afterwards. This seems to be the rallying cry of the Slow Food Movement and other present-day culinary groups dedicated to revitalizing ice cream, and to restoring its flavor and cultural significance.

**ICON FOODS.** The term “icon” was first used during the Middle Ages as a religious word suggesting images, figures, signs, or objects representing sacred elements. They were fabricated items meant to recreate or suggest something or someone consecrated or divine. Icons themselves are pictures, signs, or resemblances of seemingly more significant things or people. They are slightly different from symbols or indexes in that they have meanings of their own; however, they develop elaborate meanings when used in reference to something more significant. Icons, tangible signs of something larger, are displayed as pictures, objects, and even food, whereas indexes and symbols have meaning only in relationship to another object. It is through the icon that

people gain access and learn about the object. Icons are signs that stand for or define something else (Parmenier, 1994; Peirce, 1931).

In the twenty-first century the term “icon” often implies an object representing something else, but even this definition has evolved. Within popular culture, icons are not necessarily just representative of something else but also may be something that receives an extraordinary amount of attention, praise, and idolization. “Iconic” can also mean formulaic or repetitive, as is seen in logos and other illustrative representations. And icons themselves change meanings over time.

The word “icon” today has largely lost its religious and spiritual attachment. Rather, icons are used in secular settings. Examples of icons are found throughout popular culture in movies, books, stories, clothing, music, celebrities, and food. Specific icon foods, when consumed or even just imagined, immediately suggest links to specific places, culturally bound groups, or communities.

Icon foods are always fair game for parody, and, conversely, many icons are also themes for food. The Eiffel Tower, Leaning Tower of Pisa, and the Statue of Liberty have often been reproduced in ice cream or candy. Here we have the Liberty Bell (1876 copper mold complete with faux crack) sold under the guise of walnut ice cream at the U. S. Centennial. To the right is a George Washington cast iron cookie print (for Washington’s Birthday), which reappears as a patriotic motif on the preserve jar in “Preserves” (Volume 3, page 153), and a “Liberty” cookie mold for a New England Fourth of July picnic. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

They are used within a cultural context, exploring how specific foods mirror express groups of people, as opposed to the original religious meanings and connotations of the term “icon.” Icon foods and their images also have different meanings for different groups of people, whether grouped by nationality, ethnicity, religious affiliation, or ideological beliefs.

### Personal Identity, Group Identity, National Identity

Icon foods help define individual, group, and national identity. The difficulty here is determining whether inside members of a group deem the food iconic or outsiders consider it representative of the group.

Specific foods or food practices may serve as icons for individual people’s beliefs or values, as seen in the example of vegetarianism. Corporate identity may also be defined by food icons, as in crediting producers on restaurant menus or the use of fast-food logos. Ethnic groups are often defined by specific foods, considered quintessential to their cultures. National, regional, racial, religious, and ethnic identities are often dictated by specific icon foods. Sometimes these foods are selected by the group itself, as with the state-created Israeli cuisine; southern American grits; Louisiana “crawfish”; Maryland blue crab; Maine lobster; Florida orange juice; Massachusetts cranberries; Vermont maple syrup; Texas chili; New York bagels; Alsatian *choucroute garnie*; French croissants, cassoulet, and ratatouille; Japanese sushi, Scottish haggis; German wursts; Austrian Sacher torte; and Antiguan pepper pot. Sometimes outsiders choose foods they judge iconic for groups they are not members of, often with negative references.

### Iconic Food Logos and People

Throughout the world, but predominantly in the United States, food logos for famous food companies represent the whole of American culture and the values of capitalism and enterprise. Around the world America is synonymous with McDonald’s. The commonly recognized McDonald’s “golden arches” are a representation of modern corporate worship. Other large-scale food company logos are known worldwide also. It is not the foods themselves that suggest the country but in these cases the food businesses that symbolize entire nations. For example, Heineken, Fosters Lager, and Guinness Stout are all brands of beer, but each conjures up specific images of its home country and people, Holland, Australia, and Ireland, respectively. Similarly food clip art emphasizes the visual aspects of food over its taste. It is not the actual food but the image of the food or of the food company and what that image represents. For example, Ronald McDonald is an icon, but he is not a food, a restaurant, or even a person.

The famous Andy Warhol Campbell’s soup artwork is an example of a pedestrian food product elevated to

iconic proportions. The labels and branding of many other established and popular packaged food products, including Heinz ketchup, Tabasco sauce, Yoo-Hoo chocolate drink, and Oreo cookies, are iconic. In these examples, iconic seems to mean “has been that way for a long time.” It is recognizable. People may also serve as food or culinary icons, symbolizing the highest levels of culinary prowess (Julia Child, George-Auguste Escoffier, and Marie Antoine Carême) or representing food values (Alice Waters) or food commercialism (Emeril Lagasse).

**IMMUNE SYSTEM REGULATION AND NUTRIENTS.** Chicken soup, herbal tea, and vitamin C pills take on special meaning in cold and flu season. But beyond their possible role in treatment and comfort, nutrients are essential and fundamental parts of immune system function. To understand nutrient-immune interactions, it is helpful to understand how the body’s immune system functions in general.

The human immune system has evolved to the state where it cannot only maintain continual vigilance against new challenges, but can “learn” from past challenges and “remember” more efficient means of resolving those challenges if they are ever encountered again. The numerous cooperative mechanisms by which the immune system addresses (but does not “remember”) novel challenges are collectively termed “innate immunity.” These mechanisms include proteins that can bind to or neutralize a wide variety of foreign particles, and cells that can phagocitize foreign particles to remove them from the body. In the process of neutralizing and removing foreign particles, other cells within the immune system (mainly dendritic cells) transport samples of the foreign particles (antigens) to specialized tissues and organs (spleen, lymph nodes, Peyer’s patches) where naive cells (T cells and B cells) not previously exposed to foreign particles can adapt their surface molecules (through gene recombination) in order to increase the efficiency with which later encounters with the foreign particle can be

resolved. These adapted cells and associated specialized proteins (immunoglobulins—proteins that function as antibodies) provide immunological memory of past encounters and form what is termed “acquired immunity.”

The body’s ability to resolve infections can be likened to the running of a race. The infectious agent must elude detection by the immune system until it can proliferate and establish itself within the body. The earlier the body can detect this infection (by maintaining a critical concentration of innate immune system cells and proteins throughout the body) and the faster the body can produce new protective cells and proteins, the better the chance of winning the race. The key steps in this process—efficient communication and rapid biosynthesis—are constrained by the availability of raw material, and in the body, raw material means nutrients. In this light, well-established nutritional principles can also be regarded as immunological paradigms.

### **Biosynthesis: Building New Cells and Proteins**

The immune system is continually producing a remarkable number of new cells and proteins to provide a broad repertoire of potential immune responses and maintain functional concentrations in the periphery. An average adult has nearly six pounds of bone marrow, which produces about one trillion white blood cells per day, accounting for 8 percent or more of the total protein synthesis in the body. About 60 percent of bone-marrow biosynthesis is devoted to producing neutrophils (innate immune system phagocytes), amounting to about 100 billion cells a day, which then survive only one to two days in circulation. Studies in laboratory rats indicate that in the acquired immune system, cell turnover is ten times higher in the thymus than in the liver. Of the millions of naive T cells and B cells produced in the thymus and bone marrow every day, only about 3 to 5 percent of T cells and 10 to 20 percent of B cells pass positive and negative selection steps to reach the periphery and enter the “race” that was described.

As for proteins, more than two-thirds of the IgA (an acquired immune system protein useful in protecting mucosal surfaces—eyes, mouth, etc.) produced by the body every day (more than three grams per day for a 155-pound person) is secreted onto the body’s mucosal surfaces for short-term disposal. Immunoglobulins also account for a significant fraction of total blood protein (second only to albumin) and must be replenished continually at a rate of about six grams of immunoglobulins per day for a 155-pound person. Clearly, maintaining the immune system is a demanding process for the human body.

On the cellular level, upon activation, a lymphocyte doubles the amount of intracellular energy (ATP—that is, adenosine triphosphate) committed to protein synthesis (up to 20 percent of total cell energy use), while nucleotide synthesis begins consuming about 10 percent

of the cell’s energy. This ATP is ultimately derived from dietary macronutrients (protein, carbohydrate, or fat) through metabolic steps that require thiamin, riboflavin, biotin, pantothenic acid, and niacin. When ATP supply is limited, protein and nucleotide syntheses are the first cellular processes to suffer. The building of proteins and nucleotides from amino acids also requires folate, vitamin B<sub>6</sub>, and vitamin B<sub>12</sub> as the essential cofactors. Enzymes that build immunologically active proteins and cells also rely on diet-derived transitional metal atoms (iron, zinc, copper, etc.) for stability and to serve as functional centers. For example, ribonucleotide reductase is a rate-limiting enzyme in nucleotide synthesis, but the only way to maintain the loosely bound iron atom in its functional center is with adequate dietary iron intake. When deprived of multiple nutrients during malnutrition, these immunological processes are clearly compromised as exemplified by reduced thymus mass, lower IgA secretion, and poor proliferation of immune cells in vitro.

### **Signaling and Gene Regulation**

The ability to expand or direct an immune response depends on communication between and within cells. In the innate immune system, various cells can produce signaling molecules (eicosanoids, chemokines, etc.) that attract phagocytes to the site of a challenge (inflammation) while alerting the rest of the immune system. In the acquired immune system, the adaptation of immune cells can be directed toward more efficacious products by signals between cells (cytokines, receptor interaction, etc.) and inside of cells (intracellular signaling molecules, nuclear binding factors, etc.).

Perhaps the clearest relationship between essential nutrients and immune system signaling is the transformation of dietary essential fatty acids into eicosanoids. Certain kinds of fat, which synthesize polyunsaturated fatty acids, are essential to life. These fatty acids are classified as omega-3 or omega-6 fatty acids based on their chemical structure. These fatty acids are used by the body to manufacture eicosanoids (prostaglandins, thromboxanes, and leukotrienes) that regulate inflammation and other body functions. At a molecular level, the distinction between dietary intake of omega-3 versus omega-6 fats is functionally important since eicosanoids derived from omega-3 fats do not produce as much inflammation as omega-6 fats.

An area of immunological research that has rapidly expanded in recent years is the discovery and characterization of proteins that carry signals between the cell surface and nucleus as well as where these proteins bind within various genes. Both vitamin A and vitamin D regulate gene expression by binding to specific gene sequences including, for example, the genes that regulate production of the antiviral protein interferon-gamma. A deficiency of either of these vitamins can impair immune function. Pharmacological doses of vitamin D have been

investigated for their therapeutic potential in autoimmune disorders.

Immune system cells also initiate intracellular signals in response to oxidation. Oxidative stress induces expression of intracellular proteins (AP-1 and NF- $\kappa$ B), which leads to increased production of pro-inflammatory signaling molecules (such as cytokines and chemokines) and their receptors. Vitamin E, vitamin C, and other antioxidants can reduce NF- $\kappa$ B expression, which may contribute to their wide variety of effects on the immune system. Intracellular oxidation state also may alter acquired immune responses, but further research is needed to determine if dietary antioxidants can modify oxidation-sensitive genes and proteins.

### Life-Cycle Stages

Different stages of the life cycle have unique nutritional demands and are characterized by unique immunological functionality. Both young children and the elderly have clear age-related immune function deficiencies. In addition, many children in the United States do not meet their daily requirements for several immunologically relevant nutrients, including vitamin E, iron, zinc, and vitamin B<sub>6</sub>. The elderly may also have difficulty meeting their requirements for vitamin B<sub>12</sub>, zinc, vitamin E, iron, vitamin D, and vitamin B<sub>6</sub> as a result of physiological changes due to aging or to inadequate dietary intakes. Pregnant and lactating women are remarkable because they produce acquired immune system products for the sole apparent purpose of export to the infant. Likewise, pregnant and lactating women frequently do not meet their nutritional demands for folate, vitamin B<sub>6</sub>, iron, and zinc. Few studies have examined the interaction between nutrients and life-cycle-dependent immune outcomes in otherwise healthy people, but the available data indicate that these interactions have immunological impact—for example, vitamin E among the elderly and iron among postpartum women. Given the susceptibility of these populations to infectious disease, a better understanding of nutrient-immune life-cycle interactions is needed to promote optimal immune status through adequate nutrition.

### Nonnutritive Food Components and the Immune Response

For immunologists, developing more efficacious vaccines and certain anticancer agents is a process of improving immune system performance. As nutritional paradigms have shifted from preventing deficiency to promoting optimal health, nutrition scientists have also sought to improve immune system performance. Many *in vivo* studies have examined more or less purified food components like phytochemicals (polyphenols), herbs, and carotenoids. Such studies frequently use classic immunological tests—cell proliferation, blood lymphocyte counts, skin hypersensitivity responses, etc.—but the results of these tests should be interpreted with caution. For example, a food component that increases cell proliferation may be

beneficial if it is the protective cells that proliferate more readily. Conversely, increased cell proliferation would be harmful if autoreactive T-cell or B-cell clones were expanded or inflammatory responses were boosted inappropriately. Although these measures are useful for preliminary identification of nutrient-immune interactions, additional studies using efficacy-related immune measures (infectious disease risk, vaccine titers, etc.) are needed before such phenomena can be termed beneficial.

### Summary

To maintain immunological competence, the immune system must quickly alert the body to foreign challenges and rapidly manufacture the cells and proteins needed to stop exponentially dividing infectious organisms. It is apparent that some essential nutrients are signaling molecules. Others can be rate-limiting factors in cell division and protein synthesis. The brevity of this review has prohibited the exploration of many other important nutritional immunology topics: nutrient interactions with infectious agents, treatment of autoimmune disorders, cancer biology, and metabolic functions of nutrients unrelated to biosynthesis or signal transduction. Clearly, the most venerable nutritional paradigms of growth and development are important for shaping the magnitude and character of immune responses.

**INCA EMPIRE.** The imperial Inca state was built upon thousands of years of cultural history and diverse elaborate statecraft of the Andean region of western South America, beginning in the thirteenth century C.E. Though the empire was short-lived (it was conquered by Spain in the sixteenth century), the Inca of the Cuzco valley brought together hundreds of groups, including speakers of many mutually exclusive languages from the dry western South American coasts to the verdant Amazonian foothills, from warm and moist valleys of modern Columbia to the dry Atacama Desert of Chile and the dry mountains of northwestern Argentina. They conquered this territory in less than sixty years. Among their many tools for statecraft were food production, storage, and feasting. When they conquered they divided the lands for the state, for the sun (the focus of their religion), and for local use. In this way the conquered people had to work all of the land, though most of the produce was for the Inca rulers; produce was taken to and stored in highly regularized storage buildings called *qolqa* placed at administrative centers (*tambo*) throughout the empire. Food had great cultural value and carried the histories of the consumers in every meal. The recipe and type of plant variety used identified a person's background, much as clothing did. The Inca encouraged these differences, to keep account of the groups that they codified in a hierarchical record-keeping organization, with the local leaders reporting to Inca administrators.

All social events were marked with food and gift exchanges. These feasting activities occurred at the conquest of new peoples, but also at the renewal of group allegiances and all religious ceremonies. John Rowe notes that the value of crops was so great that at the start of planting season, between September and November, when the rains began, the Sapa Inca (king) himself would join the religious assembly to make the first hole in the ground for maize (corn) planting in a sacred field of the religious authorities. While men had to make the holes in the ground, women had to place the seed in the earth. Singing accompanied this activity, recounting major military victories. After this planting was begun, beer was provided to all workers. The crops were tended throughout the rainy season, to keep animals from eating them, until harvest, which began around May when the rains tapered off. In the highlands, harvest was accompanied by large cooked meals, primarily of potatoes, in the fields, to repay helpers.

When the Inca arrived on the borders of a group they wanted to conquer, they would send emissaries ahead to ask if the group wanted to join the Inca state or would rather fight. If the group chose to join and not fight, a date would be set for a ceremony. On that date, the Inca military leaders would arrive in the territory bearing gifts of fine clothing, elaborate imperial ceramics, and jewelry, for the new local leaders to take on the emblems of the Inca state. If the local leaders accepted these gifts and their takeover, there would be a feast of

beer and meat. These events focused on specific dishes, ceramics, and cuisine. Tamara Bray reports that there were three highly standardized receptacles to present food at these state occasions; a jar or *arybaloid*, a plate, and a cup or *keru*. The jar was to serve liquid, always a fermented beer called *chicha* in Quechua, the Inca language. This vessel shape is the oldest ceramic shape in the Andes. This beverage could be made out of many plant items, the strongest being the fruit from a leguminous tree of the warm valleys and coasts, *Schinus molle*, called *molle*. *Chicha* could also be made from quinoa (*Chenopodium quinoa*), an annual grain that grows in the high mountains, but the most common and of highest value was *chicha* from maize (*Zea mays*). (In fact, it is clear that the Inca made maize the state crop and focused much of their conquests on the warmer intermontane valleys

Ancient terraced fields at Mora, Peru. By terracing fields into the sides of steep mountains, the Inca were able to increase their food production many times over. © CHRIS RAINIER/CORBIS.

and coasts.) This beer would be consumed in highly decorated tumbler-shaped cups made of ceramic or wood. This vessel probably became an important item used in ritual consumption in the earlier Middle Horizon states. The plate was an innovation for dry food presentation in the Andes. This would be how the dried camelid meat (*charqui*), boiled potatoes (*papa*), or toasted corn kernels (*kamcha*) would have been presented. Outside of the imperial Inca feasts such dried foods would have been presented on nicely woven cloth, as is still done in the countryside in the early twenty-first century. The Inca controlled hunting of large game, primarily two kinds of deer (*loyco* and *taroka*) and guanaco, for their pleasure, making these species a less common foodstuff than in earlier times.

Most of the populace typically ate something quite different. There were two main meals a day. The first was a thick soup eaten out of bowls in the midmorning after early tending of herds. It was made of potatoes, quinoa, or maize in the highlands, depending on the elevation of the farmer, and of lima beans or maize on the coast. The highland evening meal at dusk was consumed after a day in the fields and usually was solid food consisting of beans or boiled potatoes with a spicy sauce of chili peppers and wild herbs, eaten out of a common cooking jar with wooden spoons or on woven cloth. Meat was sometimes included, but it was usually only reserved for feast days. This would often be llamas or alpacas (camelids) in the higher areas, or guinea pigs (*cuyes*), and less often wild ducks, rabbits, and other small animals caught in the fields. Along the coast, fish, shellfish, and also seaweed would have been a common soup base as well as an addition to the evening meal, again spiced with chili peppers and wild herbs.

Moghul India  
Northern India  
Southern India

### MOGHUL INDIA

Indian cuisine reached its zenith in the royal kitchens of the kings, nawabs, and maharajas—the one-time rulers of India's princely states who patronized art and culture, and enjoyed a lavish lifestyle. Among the varied cuisines that were native to India or borrowed from other world cultures and amalgamated within the Indian milieu, the one that stands at the forefront is "Moghlai cuisine," named for the era of the Grand Moghuls during which time it developed and became immensely popular. So rich and grand was this cuisine that it left a lasting impact on and influenced other equally grand cuisines—the Awadhi cuisine of Lucknow and of the Rampur royal family in North India and the Hyderabad cuisine within the state of Nizam in the Deccan region.

In spite of multiple invasions—by the Aryans in 200 B.C.E., the Greeks led by Alexander the Great in 326 B.C.E., the Moghuls in the sixteenth century, the British in the eighteenth and nineteenth centuries, and the more limited incursions of the Mongols, Huns, Arabs, Turks, Afghans, Portuguese, and Dutch in between—India still managed to establish and maintain its own unique cuisine, with that of the Moghuls being a major influence.

Muslim incursions into India began as early as 712 C.E. However, their presence only began to be felt around 1000 C.E., starting with the raids of Mahmud Ghaznavi. The first Muslim kingdom was declared in India in the twelfth century with the establishment of the "Delhi sultanate," although it was not until 1526 that Babur the Mughal, a descendant of Tamerlane and Genghis Khan, successfully invaded the Punjab and proclaimed himself emperor of India. Humayun, Akbar, Je-

hangir, Shah Jehan, and Aurangzeb, with whose death in 1707 C.E. the empire effectively came to a close, followed Babur as emperor.

During Babur's rule, a Moghul era with unparalleled power flourished. Architectural projects involving the construction of great cities, palaces, mosques, and monuments were executed in North India. This time period also marked the genesis of a "cuisine" later designated as Moghuls' cuisine in India. While cherishing their cuisine, Babur and his successors, soon titled Grand Moghuls, inadvertently enhanced many facets of Indian life. They in-

troduced a unique grandeur and style to an otherwise austere Indian hospitality.

Moghul cuisine is classified as the richest and most lavish cuisine of North India. It revolves around lamb preparations for which it is famous. Prepared with cream, luscious fruits, and almonds, and served with rich *pulao*s (preparations of rice), the gamut of lamb preparations can be described in one sentence: "A really superb North Indian cook can produce a different lamb dish for every day of the year." History, tradition, and religion have encouraged North Indian cooks to experiment with lamb

dishes. Because of their Muslim backgrounds, Moghul kitchens could not use pork. The use of beef was also actively discouraged in a predominantly Hindu country. And, neither geography nor habit permitted the ready inclusion of fish or seafood in the diet. Although Moghlai cuisine came to include some excellent chicken dishes, they never compared in quality or scope with the supreme Moghlai culinary achievement, the inspired cooking of lamb. It was mandatory that the animal be slaughtered by cutting the jugular vein with a sharpened knife and while uttering the name of Allah. The meat produced from this type of slaughter, that is, by bleeding the animal to death, was called *halal* meat.

To the somewhat austere Hindu dining ambience, the Muslims brought a refined and courtly etiquette of both group and individual dining, and of sharing food and fellowship. Food items indigenous to India were enriched with nuts, raisins, spices, and ghee (clarified butter). These included meat and rice dishes (*pulaos*), dressed meats (kebabs), stuffed items (*samosas*), desserts (*halwa* and stewed fruit), and sweetened drinks (*falooda* and sherbet). New dishes enriched the cuisine of the land, like those made of wheat finely ground with meat (*halim* and *harisa*), the frozen *kulfi*, a rich ice cream of milk solids, or the *jalebi* (a sweet made from gram flour, which is deep-fried and sweetened in sugar syrup). The Muslims influenced both the style and substance of Indian food.

Moghlay cuisine consists generally of *sharbat i labgir* (a very sweet sherbet), *naan e tanuk* (light bread), *naan e tanuri* (chapatis cooked in tandoors), *samosas* (whole wheat pastry stuffed with meat, onion, etc.), mutton, the flesh of birds such as quail and sparrow, *halwa*, and *sabuni sakar* (a mixture of almonds, honey, and sesame oil). Wine was also customarily served. After the meal, it was customary to serve betel leaf to refresh the palate and to aid digestion.

Vast table settings and spreads were commonplace. However, most eating was done by hand, although spoons and knives were used for serving and carving. The hospitality of the elite Moghuls was legendary. It was often the case that a nobleman's entire staff would be fed their main midday meal at his home. This would comprise *naan* (bread baked in a tandoor), goat meat, chicken *biryani*, a cup of wine, sherbet, and betel leaf. Frequently, the nobles ate their meals together and the unconsumed food would be distributed to beggars.

During the reign of Akbar, there were three classes of cooked dishes. The first, called *safiyana*, was consumed on Akbar's days of abstinence. No meat was eaten on these days, and the dishes were either rice- or wheat-based. The rice-based dishes included *zard birinj* (saffron rice), *khuska* (boiled rice), *khichri* (a dry preparation of rice and lentils cooked together), and *sheer birinj* (rice cooked with milk and sweetened). The wheat-based dishes included *chichi* (essentially the gluten of wheat isolated by washing and then seasoned). Also included in the

meal were lentils, *palak saag* (spinach), *halwa* (a generic name for a dessert made by cooking one ingredient like carrots with milk solids and clarified butter, and then sweetening it with sugar), and sherbets. Both meat and rice cooked together, or meat and wheat prepared together, constituted the next set of dishes. Those with rice included *pulaos*, *biryani*, *shulla* (a spicy mix of rice, lentils, and meat), and *shurba* (a thick soup). Those with wheat included *halim* and *harisa* (both are made by pounding wheat and meat together with spices), and *kashk* and *qutab* (both prepared with meat and wheat with different spices). The third class of cooked dishes were those in which meat was cooked with *ghee* (clarified butter), spices, curd, eggs, and so forth, to yield dishes such as *yakhni* (a mutton preparation), kebabs, *dopiyaza* (literally, "twice onions," once at the start of cooking in ground form and then later sliced and fried), *mussaman* (a mélange of minced meat, onions, herbs, and spices used as a stuffing), *dumpukh* (meat or vegetable dry-cooked in a heavy-bottomed, tightly sealed pan on a slow fire), *qaliya* (a meat dish cooked with a vegetable, in which the gravy is thick and saucelike), and *malghuba* (a spicy meat dish).

Variations of bread served were either thick, made from wheat flour and baked in an oven, or thin, made from unleavened dough and baked on iron plates using a dough of either wheat or *kbushka* (boiled rice). The Persian Muslims preferred leavened bread baked in an underground oven. The *paratha* (whole wheat bread, layered with fat and baked on a griddle) was an adaptation of the deep-fried *pooris* (whole wheat dough, rolled out and deep-fried). The more affluent Muslims ate *baqar khani* (leavened bread enriched with clarified butter), whereas *shirmal* (a sweet baked bun-type bread) was even more upscale than *baqar khani*.

Raw materials came from various places: rice from Bharaj, Gwalior, Rajori, and Nimlah; *ghee* from Hissar; ducks, water fowl, and certain vegetables from Kashmir; and fruits from across the northwestern borders as well as from all over the country. Babur's personal fascination with Indian fruits was evident in his description of them, his names for the fruits sometimes making a technical comment on their variety: the citrus phylum-orange, lime, citron, *santhra* and *galgal* (both are species of orange), *jambiri lime* (rough lemon), *amritphal* (perhaps the mandarin orange), and *amal bid* (a citrus fruit).

A favorite breakfast for common Muslims was *naan* accompanied by *kheema* (minced meat) or kebabs. Rice and onions, and rice-based desserts, such as *phirni* (rice flour cooked with milk and sweetened), *sheer birinj* (rice and milk cooked together and then sweetened) blended with milk and sugar, *halwas*, and dried fruits were other delicacies. The Muslims also adopted the Hindu habit of chewing betel leaves stuffed with areca nuts and spices after a meal.

Eminent citizens who lived in grandeur relished serving opulent preparations, which could number as

many as fifty types at a time. Most of the preparations served were those inspired by the Persians and Iranians, and included such dishes as *khormas* (meat, chicken, or fish with a sauce of creamy consistency), kebabs, *rotis* (unleavened bread), and *pulaos*. The marriage of the Persian Princess Noor Jehan to Indian Prince Jehangir also contributed to the import of many delicacies to India and this had its own profound effect on Moghul cuisine.

The art of retaining the rudimentary character of a food preparation while incorporating multiple seasonings was mastered by Indian chefs. A classic illustration is the preparation of Moghlai *biryani*. This dish is also a model for the fusion characteristic of cooking from a bygone era. Two odd or incompatible ingredients—rice and lamb—were not only marinated, but also married with spices, curds, saffron, an aromatic mixture of spices, and garnished with *varq* (silver leaves).

Although there is room for modification or different styles in *biryani*, its basic formula is as steadfast as that of another speciality, kebabs. Through the multiple processing of lamb, which was minced, steamed, skewered, broiled, cubed, or sliced, Moghul chefs demonstrated great dexterity in the preparation of this dish. The two most popular dishes in the kebab family were *shammi* kebab (a combination of minced lamb, nuts, and chickpeas, stuffed with chopped onions and green chilies) and *nargisi* kebab (a hard-boiled egg covered with a preparation of minced lamb, onions, spices, and herbs, and then deep-fried).

Chefs were trained to present their food as impressively as possible. Some even went as far as preparing *khibbri* (a rice and lentil preparation) with almonds and pistachio nuts, which were cut to resemble grains of rice and lentils. This was all done for visual effect. Colors also played a major role in food presentation. Various permutations and combinations were used to make the appearance of the dish as attractive as the taste.

The Moghuls introduced rich, milk-based sweets in India. Tiny bits of bread coated with sugar and ghee were prepared for the ceremonies of *Fatiha* (prayers offered to one's ancestors) and *Niyaz* (prayers offered to the Prophet). *Malida* (a sweet made with broken bread, sugar, and ghee, although the bread is often replaced with semolina) was another sweet dish. Gradually, milk, which had been thickened by boiling it down, replaced flour in the preparation of sweets. The Moghuls were also fond of candies and preserves. During their reign, *murabbas* (sweetened preserves) and *achars* (pickles) were developed and commonly used. *Hakwa*, a sweet item, would be made with a variety of ingredients, from which it would take its name. For instance, if made from carrots, it would be called “carrot” *hakwa*, if made from lentils, it would be called “lentil” *hakwa*, and so on. *Hakwa* is said to be of Arab origin. The most popular *hakwas* with the Muslims were *soban* (a sticky wheat confection), *papri* (a crispy sweet confection made with wheat and sugar), *habshi*

(made with wheat, reduced milk, and sugar), and *dudhia* (made with bottle gourd, reduced milk, and sugar). *Barfi* (a dry, white, soft sweet like a milk cake) originated in Persia (*baraf* means snow in the Persian language). *Balu shahi* (a sweet, glazed wheat patty), *khurme* (a date-shaped sweet), *nukhtyan* (a sweet dish made of wheat and sugar shaped as small beads), *gulab jamun* (croquettes made of milk solids, deep-fried until golden brown, and then soaked in sugar syrup), and *dar behisht* (a sweet dish of rice flour and thickened milk) were all developed during this era. *Jalebis* originated in Arabia, where they are called *zalabia* (a gram flour batter, piped out in circles in hot oil, deep-fried until crisp, and then soaked in sugar syrup).

Food that was served at feasts at home or transported to another setting was called *tora*. This comprised a *pulao* (a rice-based dish); *muzafar* (a sweet, rich rice dish flavored with saffron); *mutanjan* (meat, sugar, and rice with spices); *shirmal* (a sweet baked bun-type bread); *safaida* (a simple sweet rice dish); fried aubergine; *shir birinj* (a rich sweet rice dish boiled in milk); *qaurma* (a meat curry); *arvi* (a fried vegetable with meat); *shammi kababs* (croquettes of meat and lentils); and *murabba* (sweetened preserves), *achar*, pickles, and chutney.

Regional environments influenced dietary rituals in India. Meat or any type of flesh is forbidden after a funeral. No food is cooked in the house of mourning for forty days after the death. Women who are seven months pregnant receive vegetables, dried fruit, and cake on their laps. After an engagement ceremony, dates and sugar are distributed to the family of the groom-to-be. At the wedding, the bride and her kinswomen eat from the same plate, a practice that would be unthinkable in the Hindu world. Islamic festivals such as *Bakrid*, *Id*, and *Moharram* are celebrated all over India. The foods consumed by the community have a strong Islamic influence. *Maleeda* (broken bread, sugar, and ghee) is a common ritual offering.

The Moghul emperors relished the practice of eating *paan* (betel leaf). Two betel leaves formed one *bira*: One leaf was stuffed with *supari* (betel nut) and *kattha* (*Acacia catechu*, heartwood extract), and the other leaf would have *chuna* (lime). Sometimes, the betel leaves contained *kapur* (camphor) and musk. When chewed, this sweetened the breath and reddened the lips. *Paans* were bestowed as a mark of royal favor on courtiers. By the end of the seventeenth century, a *paandaan* (a container for betel leaves and other ingredients) was given as a royal present to ambassadors and nobles.

The Moghul emperors favored water from the Ganges River. People with the highest integrity oversaw the transportation and distribution of water, from the source to its points of consumption. The water was tasted before consumption as a precautionary measure against poisoning. The use of wine was neither prescribed nor forbidden in the Mughal fraternity.

Devout Muslims celebrate three main festivals, each of which is replete with its own food requirements:

- *Ramadan* is observed as a time of fasting and austerity. During this period, Muslims fast from sunrise to sunset, breaking their fast only with the setting sun. The month culminates in the festival of *Id al-fitr*, where alms are distributed. Traditionally, *sheer qurma* (a sweet dish of milk, vermicelli, nuts, and dried fruits) is made on this day and offered to family and guests. *Haleem* and *bareesa* are other dishes that are commonly eaten at this celebration as they are very nutritious.
- *Id uz zuba*, or *Bakrid*, commemorates the sacrifice of Ishak by prophet Ibrahim in the name of God. However, God instructs Ibrahim to sacrifice a ram instead. On this day, Muslims sacrifice lambs, goats, rams, and cows and feast on ritual *pulaos*, *biryanis*, curries, and roasts. These are then sent to family and friends not in attendance.
- *Muharram* is observed in honor of the saint Hussain, who fell in battle against Yazid, the tyrant ruler of Arabia. Meat is strictly avoided on this day. *Khubooli* (a simple austere dish of rice and chickpea lentils), yogurt and rice, and *zarda* (a sweet dish made with rice) are prepared and offered in prayers.

### NORTHERN INDIA

India is a vast country. Its geography and climate vary tremendously, from the landlocked mountains and the fertile Indo Gangetic plains in the North, to the arid Decan plateau and the coastal regions of the South. It is these differences that have given India a rich and varied tradition of food.

India is made up of people from several faiths, and the gulfs between them are substantial, including dietary customs and prohibitions. Thus, the Hindus and Sikhs will not eat beef; the orthodox Hindus and Jains avoid

onion and garlic, considered “passion-inducing”; the Parsis, who came to India in the seventh century from Persia, gave up eating beef as a gesture of thanks to the Hindu ruler who gave them asylum; and the Muslims and Jews abstain from pork but relish beef, the meat of sheep, and chicken.

Although India is associated strongly with the concept of vegetarianism, which came into being with the advent of the faiths of Buddhism and Jainism in the sixth century B.C.E., the majority of people in India are, however, nonvegetarian. In Punjab, chicken, lamb, and goat meat are relished, and in Kashmir, the Kashmiri pundits are known for their love of meat and famous *wazwans* (feasts), where up to thirty nonvegetarian courses may be served. Nonetheless, in most Indian families where meat is consumed, this occurs no more than one day a week, usually on a Sunday afternoon. For many other families, meat is consumed only three or four times a year, usually at weddings. In many middle-class families in the North, it is common to find women who do not partake of meat, fish, or eggs, while the men in the family do. The consumption of meat in these areas is sometimes associated with masculinity.

### Outside Influences

India is a melting pot of people of all religions and races, its diversity resulting from countless invasions and migrations, including those of Alexander the Great (356–323 B.C.E.). Invaders came in search of wealth and soon discovered India’s spices.

The food of North India was greatly influenced by the Persians, who entered India in the eleventh century. From the thirteenth to sixteenth centuries, Mongolian conquerors brought with them Afghan and Persian cuisine, the rich and fragrant foods of their regions. This marked the start of luxurious eating. Pilafs and *biryanis* (meat-based pilafs), garnishes of *varak* (sheets of pounded silver), spicy *kormas* (braised meat in creamy sauces), *koftas* (grilled, spicy meatballs), and *kababs* graced the tables of the emperors and intermingled Hindu and Muslim cuisines: the meat dishes of the Middle East combined with the spicy gravies that were indigenous to India. And, Muslim *naans* (bread cooked in a tandoor) and *chapatis* (bread cooked on a griddle) were consumed side by side with the more traditional *pooris* (bread made from whole wheat flour and fried in oil) and *bhathuras* (bread made from white flour and yeast and then deep-fried in oil). The idea of ending a meal with a confection also originated in the Middle East. Most of these were made of almonds, rice, wheat flour, or coconut, sweetened with sugar, and scented with rose water.

More recently, Indian cuisine has been influenced by the British, particularly in certain sections of society, such as the army and among educated, urban professionals. They institutionalized the use of white bread, as well as sandwiches, toast, and tea drinking.

## SUSHRUTA SAMHITA

The *Sushruta Samhita* is an ancient Ayurvedic text, dating back to 600 B.C.E. This traditional healing practice originated almost five thousand years ago, and its theory influenced Greek and Chinese medicine. According to Ayurvedic theory, the human body is made up of five elements: air (*vayu*), water (*jala*), fire (*agni*), earth (*prithvi*), and space (*akash*). These combine to form the constitution of the body. Any imbalance in this constitution produces disease, and Ayurveda aims to correct such imbalances by the use of suitable counter-substances.

Food plays an important role in countering the imbalances. There are six basic tastes, which are made up of two elements each: sweet (earth and water), sour (fire and earth), salty (fire and water), bitter (space and air), and astringent (earth and air).

As these elements also form the constitution of the body, the choice of food should be such that it reduces the predominant elements within the body, so that a balance exists between them. When the elements are in equilibrium, one will enjoy good health. However, what may be beneficial for one person might not suit another. Diets therefore vary from person to person, depending on age, sex, climate, and other variables.

The *Sushruta Samhita* suggests that foods be varied in taste according to the season: spring (pungent), summer (sweet and cold), monsoons (salty and sour), autumn (sweet), and winter (pungent and oily). The use of correct foods in different seasons will presumably prevent the onset of disease.

## Seasonality of Cuisines

The well-defined seasons of India bring with them a series of particular fruits and vegetables. Thus, menus and diets vary considerably year round—from lush berries in the early days of summer to ripe watermelons available during the later hot weeks of the same season. Certain seasons are associated with specific foods, according to the *Sushruta Samhita*, an ancient medical text, written around 600 B.C.E. It recommends pungent foods in spring, sweet and cold in summer, salty and sour during the rains, sweet in autumn, and greasy and hot in winter.

In Kashmir, where the winters are cold, the staple diet of meat, fish, and rice is supplemented with vegetables that have been sun-dried during the summer months. Seasonality also extends to herbs and spices. During the cold months of winter, “heat-generating” spices like cinnamon, cardamom, cloves, black pepper, and chilies are used in cooking to keep the body warm. Mace is consid-

ered taboo in summer, whereas poppy seeds are regarded as cooling during the summer months.

## Foods of the Northern Region: Kashmir, Punjab, Uttar Pradesh, and Rajasthan

Traditionally, Indian food is served as a complete meal in one course. It is composed of several vegetables, a *dal* (a purée of lentils), and a central starch, which is the main source of calories. Yogurt, relishes, and chutneys are served on the side. In the North, the starch is unleavened bread, such as *chapati* (a flat griddle bread). People in the North tend to eat more wheat and maize, which are easily available and made into bread.

Pulses high in protein, carbohydrates, and fiber have always played an important part in the diet of Indians. For vegetarians, pulses provide essential proteins.

The most commonly eaten meats are chicken, mutton, and fish. A rice-based sweet usually signifies the end of a meal. Savory and sweet snacks are very popular, but do not correspond to specific meals or dishes. Northern India has a great tradition of “snacking.”

Alcohol is not consumed along with food, but iced water or *lassi* (a yogurt-based drink) usually accompanies the meal. Aperitifs like *kanji* (made from fermented carrots and mustard seeds), *aam panna* (raw mango juice), *jaljeera* (made from tamarind juice and cumin seeds), and *nimbupani* (fresh lime juice) are the favored drinks in the North.

North Indians place great emphasis on the use of milk and milk products in their cuisine. This is particularly true of the Punjabis, who use a great deal of ghee

## SNACKING IN INDIA

Indians love to snack and have a penchant for light, spicy foods. This has given rise to a whole new cuisine called *chaats*, a generic name for several salty snacks that originated in Delhi. They leave a spicy, lingering taste in the mouth and are usually eaten during mid-morning or at teatime.

*Chaats* come in a wide variety of savory tidbits, spiced mainly with *ajwain* (bishop’s weed). They are consumed with two chutneys: the fresh and tangy mint chutney and a tamarind-based chutney called *sonth*. Most chutney preparations are vegetarian and have potatoes and/or lentils as the base. Almost all have some fried components. *Chaat* tends to be bought rather than made at home, and is eaten at roadside stalls, where it is served in bowls made out of leaves.

## THE TANDOOR AND TANDOORI CUISINE

Tandoors are clay ovens that are air-dried, embedded in sand or earth, and fired with either wood or charcoal at the bottom. The heat generated is distributed up the sides of the oven. The average temperature within a tandoor ranges between 1,112 to 1,472°F (600 to 800°C). Some tandoors can withstand extreme heat, up to 2,552°F (1,400°C).

Tandoors are most commonly used in Punjab. It is a versatile piece of equipment and can be used to cook meats, kebabs, breads, and *dal* (lentil purée) with equal ease. Over recent years, there have been variations in the types of tandoors available: from gas-operated models to electric ones. However, in the final analysis, the flavor from the original charcoal-fired tandoor is unsurpassable. Tradition holds that a tandoor in regular use improves the flavor of anything cooked in it, because the heated clay releases a mellow fragrance that permeates the food. In the case of meats, the final taste is a result of the smoke that emanates from the marinade which has dripped on the hot charcoal.

Tandoors are used to cook a variety of meats and breads. The prerequisite for cooking meats in the tandoor is that they must be marinated. The popularity enjoyed by Indian cuisine around the world can be attributed, in large measure, to the tandoor, because it uses very little oil or fat for cooking and the foods thus cooked are moderately spiced.

Prior to use, the tandoor has to be seasoned. This is done by rubbing the inside walls of the tandoor with a paste of spinach or any other green, leafy vegetable. After this has dried, a mixture of mustard oil, butter-milk, jaggery, and salt is applied over the paste. The tandoor is then heated by lighting a small fire at the base, so that the temperature rises gradually. If the temperature rises too fast, the internal walls will crack and it will not be possible to control the temperature. Once heated, the mixture will peel off, and it has to be reapplied three or four times to properly season the tandoor. Finally, the inside walls need to be sprinkled with brine and allowed to dry.

(clarified butter), white butter, *paneer* (homemade cottage cheese), and cream in their cooking. For those who cannot afford or tolerate ghee, the preferred oils are mustard and peanut.

Tandoori cuisine has its origins in the northwest frontier province, now in Pakistan. The cuisine gets its name from the tandoor (the oven in which the food is

prepared) and has contributed to the growing popularization of Punjabi cuisine throughout the world. In many cases, tandoori cuisine is synonymous with Indian cuisine.

## Northern Indian Cuisine by State

**Kashmir.** Kashmiri cuisine is a unique blend of Indian, Iranian, and Afghani cuisines. It is essentially meat-based and centered on a main course of rice. Unlike the Brahmins in other parts of the country, the Kashmiri Brahmins are nonvegetarian.

The abundance of dried fruit and nuts (walnuts, dates, and apricots) in the region has inspired their use in desserts, curries, and snacks. Sauces for curries are made from dairy-rich products.

A local spinachlike green called *baak* is popular in the summer months, as are lotus roots, which are used as a meat substitute. Fresh vegetables are abundant in the summer, including a prized variety of mushrooms called *gubchi*, used only for special occasions. Fresh fish is favored in the summer, while smoked meat, dried fish, and sun-dried vegetables are used in the winter.

Kashmir is also known for a very special green tea called *kabwa*, flavored with saffron, cardamom, and almonds and served from a samovar, a large metal kettle, which originated in the Russian steppes.

**Punjab.** Punjabi cuisine is simple, substantial, and robust, reflecting the extremes in climate and the industrious nature of its people. It forms a distinctive part of the culture. Everyday meals are centered on bread; there are a great variety of flat breads. *Parathas* (breads that are plain or stuffed with shredded, seasonal vegetables, seasoned with herbs and spices, and baked on a hot griddle) are favored for breakfast, served with a dollop of home-made butter.

Main meals throughout the year would comprise one *dal*, at least one seasonal vegetable, *chapatis* or *parathas*, and yogurt. *Lassi* (a yogurt shake) accompanies the mid-day meal, and pickles are served on the side. Some of the more popular dishes include a variety of locally grown legumes and *dals*, cooked whole or split, *saag* (spinach), *mutter paneer* (homemade cottage cheese cooked with peas), and *baingan bhartha* (smoked eggplant cooked with tomato). Punjabis are fond of nonvegetarian food like tandoori chicken, chicken curry, and meat *koftas* (meatballs in gravy). Sweets are welcomed; carrot *halva* (grated carrots cooked with milk solids and clarified butter and garnished with almonds) served hot is a favorite in winter, while chilled *kheer* (rice pudding) is popular during the summer. *Makki ki roti* (corn bread) and *sarson ka saag* (mustard greens) served with white butter is another well-liked winter dish. Rice, which is prepared only for special occasions, is rarely served plain. It is made with cumin or fried onions or, in winter, jaggery. Punjabis prefer aromatic basmati rice, especially at banquets and large social gatherings.

Bakarwal gypsy family preparing chapatis over a camp fire at Sonamarg, India. The Bakarwal gypsies are a nomadic group who travel between the Jammu lowlands of India and the mountains of Afghanistan. © LINDSAY HEBBERD/CORBIS.

*Dhabbas* are roadside eateries, commonly found on the highways in North India, particularly in Punjab. They were formerly frequented by truck drivers, criss-crossing the vast subcontinent in search of a hot, home-cooked meal. Today, *dhabbas* have sprung up not only on the highways, but also in urban areas as well, and are frequented by a cross section of society. They typically have a limited menu of one *dal*, one vegetable, and one meat dish served with a variety of breads. The menu varies daily and the food cooked is always fresh because refrigeration is lacking.

**Uttar Pradesh.** This state is best categorized by the cities of Benaras (Varanasi), which is traditionally Hindu in character, and Lucknow, which is traditionally Muslim in character.

Varanasi is one of India's holiest cities, bisected by the Ganges River, the waters of which are said to wash away a lifetime of sins. Many Hindus use the water from the Ganges for cooking and for sacred ceremonies. Breakfast in Varanasi consists of *pooris* (whole wheat bread that puffs up when deep-fried) or *kachoris* (whole wheat bread stuffed with split peas or fenugreek greens and deep-fried), eaten with *aloo bhaji* (potatoes spiced with ginger, cumin, and dried mango powder) or *aloo koda* (a combination of potatoes and pumpkin). Meals tend to be vegetarian and stick to the following formula: one *dal*, one or two seasonal vegetables, *chapatis* or some other form of traditional bread, yogurt, with side dishes of pickles and relish. People in this region are very fond of sweets, and a variety are available year round. These in-

clude *malai gujiyas* (sheets of reduced milk, folded over mounds of sweetened nuts), *lal peras* (deep red, caramelized sweetmeats), and *malpuas* (sweetened pancakes).

In Lucknow, a typical breakfast consists of *parathas* (whole wheat bread plain or stuffed with shredded vegetables and baked on a griddle) or *kulcha* (flat sour dough bread), eaten with spicy fried liver and *andey ki bhujia* (scrambled eggs cooked with chopped onions, tomatoes, green coriander, and green chilies).

The average middle-class family will eat a *salaan* (meat gravy with a seasonal vegetable), a vegetable *bhujia* (a dry preparation of vegetables), boiled rice, and *dal* for dinner. The upper-middle-class family will supplement this with a kebab or another meat dish and *kheer* (a creamy, chilled rice pudding). Occasionally, a *korma* (meat curry) replaces the *salaan*, and a *biryani* or *pulao* replaces the more ordinary boiled rice. For those with a sweet tooth, the typical summer sweet is a *guramba* (unripe mangoes cooked with sugar and semolina), and during the winter, *rasawal* (rice cooked with sugarcane juice). Family dinners tend to be very elaborate. Lucknow is also well known for its kebabs, particularly the *kakori kebab*, which is made by pounding meat and fat until it becomes a paste. To this poppy seeds, cloves, and other ground spices are added, and the pounding continues until the meat turns almost gluey. This mixture is then wrapped around skewers and grilled over live charcoal.

**Rajasthan.** Rajasthani cuisine has been influenced by the availability of food resources in the desert state and by the warlike lifestyle of the Maharajas. The food had

to be cooked in such a way that it would last for several days when the men went off to war. The scarcity of water gave rise to a cuisine that is cooked with very little or no water. This is especially true of the desert belt, where milk, buttermilk, or ghee is often substituted for water.

The princely families of Rajasthan were obsessed with *shikar* (hunting) and enjoyed game. Their meat delicacies are incomparable. During the hunts, meats, including poultry, game, and fish, are marinated, skewered, and grilled over live fires to make *soola kebabs*. Within the ancient palaces, the recipes were a closely guarded secret. Game is cooked in several ways. Rabbit, deer, and boar are prized, and what is not consumed is pickled for later use.

At the other end of the spectrum are the Marwaris, who are strict vegetarians and will not even use garlic and onion in their cuisine. Dried lentils and beans from indigenous plants are the staples of a Rajasthani diet, as wheat and rice do not grow in the desert. *Bajra* (millet) and *makki* (maize) are used for making various kinds of bread. The Marwaris use a lot of pulses and gram flour in their cuisine as vegetables are scarce in the desert climate. *Moong dal khilni* (a dry preparation of lentils, tossed in a mixture of spices), *moong godi ki subzi* (grape-sized dumplings of green gram, which has been ground to a paste and sun-dried), and *gatte ki subzi* (rolls of gram flour, steamed and cooked in buttermilk sauce) are delicacies in this region. Other innovations include the use of mango powder as a substitute for tomatoes, and asafoetida, to enhance taste in the absence of garlic and onions. Sweets are also very popular.

### Feasting and Fasting

A proverb in North India says “after a fast, a feasting; and after a feasting, a fast.” Festivals in India always revolve around food: either through feasting, fasting, or feeding someone. They are numerous, and celebrate harvests and the prevalence of good over evil in stories related to gods and goddesses. Food is an important part of any celebratory event. No festival or celebration is complete without sweets, which are said to ward off evil spirits. In North India, some of the popular festivals are Lohri, Holi, Janmashtami, and Diwali.

Lohri (the winter solstice) is a festival connected to the solar year. It is also celebrated as a harvest festival in many parts of the country. *Til laddus* (a sweet made from sesame seeds) is distributed among family and friends and eaten throughout North India. *Til* is considered auspicious and “heating,” an important attribute given the cold weather prevalent at that time of year. Another traditional preparation on this day is *khichari* (a preparation of rice and lentils cooked together).

Holi is the festival of color that celebrates the end of winter and the coming of warm weather. The crops have been cut, threshed, stored, or sold. People of all ages celebrate by throwing color on each other. The festival

is also celebrated with special sweets. In the North, families and friends share *gujiyas* made with *khoya* and nut stuffing (wheat pastry with a stuffing of milk solids and nuts) and sugar *batashas* (sugar flakes). *Thandai*, a chilled, milk-based drink flavored with almonds, cardamom, rose petals, and whole pepper, is synonymous with Holi and is routinely served to all celebrants or guests.

Janmashtami is associated with Krishna. The food prepared on this day is prepared from milk and curds, much beloved by him. A part of the festivities includes filling a large earthen pot with milk, curds, butter, honey, and fruit and suspending this pot from a height of between twenty and forty feet. Sporting young men and boys form human pyramids to bring the pot down and to claim its prized contents. Many families fast on this day, but one meal is allowed. This meal includes fruit, sweets, nuts, and curds.

Diwali, the festival of lights, commemorates the victory of good over evil. It is also the day when Lakshmi, the consort of Vishnu and the goddess of prosperity, is worshiped. Lakshmi and Vishnu are said to dwell in the celestial *Kheer Sagar* (the ocean of milk). This is the origin of the word *kheer*, a popular confection of milk and rice that is prepared on almost all festive occasions as an auspicious offering to placate the gods, after which it is served to the priests and guests. The preparation of *kheer* is a must on Diwali.

Diwali signifies the onset of winter. The harvest is over, and it is time for a change in diet that is more appropriate to the winter season. On this auspicious day, unleavened bread, which is traditionally baked, is fried, perhaps to symbolically display prosperity with the extravagant use of fat. This may also be because during the winter months, the body requires more calories to combat the cold, and richer foods become easier to digest. The affluent eat dried fruits, nuts, and sweetmeats, while others gorge themselves on *kheel khilone* (puffed rice and candied sugar figurines). There is a great emphasis on sweets, with gifts of sweets exchanged between family, friends, and business associates.

The most elaborate festival has to be Wazwan, a Kashmiri feast, that was introduced to India about five hundred years ago from Central Asia. It is a blend of the culinary styles of the Mughals and Persians who were Muslim on the one hand, and the Kashmiri pundits who are Hindu Brahmins on the other hand. As many as forty courses may be served during Wazwan, with at least twelve and up to thirty courses being nonvegetarian.

There are numerous fasts in India. Each day of the week is dedicated to one of the many Hindu deities. Those with particularly strong religious sentiments fast on the day dedicated to their favorite deity. For example, those who believe in Hanuman will fast on a Tuesday. These fasts require that only one meal, without cereal and salt, be eaten throughout the day, although fruit, nuts, sweets, curds, and liquids are allowed. Muslims in

## KASHMIRI WAZWAN

A Wazwan is a Kashmiri feast held to celebrate any occasion. It is a formal affair, and the number of people invited to attend could exceed one thousand, depending on the occasion and the social status of the host.

The Wazwan is a blend of cuisines of the Kashmiri Pundits, Mughals, and Persians. The concept of the Wazwan is more than five hundred years old and has its roots in Central Asia. The central starch for the meal is rice and there are several meat preparations. The Wazwan often includes up to forty courses, of which at least twelve and as many as thirty may be meat-based.

Traditional cooks called Wazas prepare the elaborate meal. Being a Waza is hereditary; it is passed from father to son. Four senior Wazas are required along with twelve assistants to prepare the feast for one thousand guests. If the Wazwan is a dinner, they start cooking at sunrise and continue preparing food until sunset. For a lunch, the Wazas arrive the previous evening and cook through the night.

The planning of the feast can take days and the cooking many hours. It begins early in the morning and continues throughout the day, with a whole retinue of people including butchers and assistants working to prepare the meal. There are no shortcuts in the preparation of food. The sheep are slaughtered using the *halal* method (bleeding the animal) on the day of the feast. Different cuts of meat are used for different preparations: ribs for *tubbak maz* (ribs simmered with black cardamom, turmeric, and salt, and fried in clarified butter); marrow bones, neck, and rump as well as the breast for *rogan josh* (meat curry

simmered in yogurt with red kashmiri chilies and saffron); various cuts of meat for *seekh kebabs* (minced meat ground with spices and grilled on skewers); and meat from the backbone and tail for *aab ghosht* (meat cooked in a milky sauce). All the fat trimmed from the meat is saved for the preparation of *gushtaba* and *rishta kebabs*. These are prepared by pounding the meat and fat separately to a paste. To every kilogram of meat, 250 grams of fat are added, and the pounding continues with the addition of black cardamom and other spices. These are then formed into smooth round kebabs (a quarter pound for each *gushtaba* and half that size for each *rishta kebab*) and simmered in huge cauldrons with yogurt, whole spices, and salt.

The vessels used for cooking are like the large, flat copper platters used to serve the food; many of them have a traditional *chinar* (maple) leaf design on them. The guests sit on the floor around the plates: four guests to each plate. The Wazas serve the food: In addition to all the meat preparations, there is also *haak* (a green, leafy vegetablelike spinach), tomato *paneer* (cream cheese cooked with tomatoes), various chutneys like green chili and walnut, as well as plain yogurt. *Gushtaba* marks the end of the meal. The sweets generally served include *sooji ka halwa* (a semolina sweet cooked with clarified butter) and *phirni* (a rice flour and milk dessert). Finally, hot cups of *kahwa* (green kashmiri tea flavored with saffron and cardamom and garnished with sliced almonds) are poured from samovars to aid in the digestion of the feast.

India observe Ramadan and fast for the entire month, rising at 4 A.M. to eat a small meal and breaking their fast at sundown with a full meal, including meat. This fast does not permit the consumption of food or drink throughout the daylight hours.

Another rigorous Hindu fast is *karwa chauth*. Punjabi women observe this fast for the welfare of their husbands. They wake up before sunrise and eat *sargi* (food that has been given to them by their mothers-in-law). This includes one pasta item, fruit, sweets, and *matthis* (fried savory made from flour). Throughout the day, they are not permitted to eat or drink anything until moonrise. Then, after prayers, a full meal is allowed.

### Religious Significance of Food

**Rice.** Rice has an important place in Hindu religious ceremonies. During weddings, it is thrown into the fire

because it is the symbol of fertility. When the Hindu bride leaves her maternal home for the last time, she throws fistfuls of rice over her head, signifying the riches of her childhood home. Similarly, when she enters the home of her husband for the first time, she knocks over pots of rice that line the entrance to the house. The extent to which the grains spill across the floor denotes the prosperity the bride will bring to her new family.

Rice is also a traditional dish in the daily menu offerings at the temple. Legend has it that an ancient king dreamed Lord Jagannath had asked him to introduce boiled rice in the menu at the temple. The monks, unwilling to partake of the plain food, even when the king told them of his dream, decided to feed it to a dumb monk first to see if he regained his powers of speech before accepting the rice as temple food. According to legend, not only did the monk retrieve his powers of speech, he also recited all the verses from the Vedas.

**Mango.** Mango leaves and fruit also have religious connotations. It is said that mango is the favored fruit of Ganesha, the deity who can remove any obstacles. All those who wish to have their desires fulfilled string a garland of mango leaves on their front doors.

**Ghee.** Because it is considered pure, ghee has great religious significance. It is used in all Hindu ceremonies, burned in every temple lamp, and used during cremation.

**Kara Prasad.** Associated with the Sikh community of Punjab, an offering (or *prasad*) of wheat flour, clarified butter, and sugar in equal amounts is made to the gods symbolizing universal brotherhood. During its preparation, hymns are sung in the food's praise. The *prasad* is made and served by devotees at the *Gurudwara* (a Sikh place of worship); it seeks to break down barriers of caste.

#### SOUTHERN INDIA

Southern India has been exposed to a variety of enriching influences through the years, including a number from Southeast Asia and Africa. Coconut and banana derive from Southeast Asia, betel leaf, areca nut, sago palm, and certain yams from Africa. Although the six tastes enjoined by Vedic practice are still more or less observed during a meal in most parts of India, the actual order in which the items are eaten differs from region to region. Broadly speaking, the South has a common order, and the arrangement of food items on a banana leaf used for eating is similar in Andhra Pradesh, Karnataka, Tamil Nadu, and Kerala.

##### Andhra Pradesh

The food from Andhra Pradesh is renowned for its sharp and pungent flavor. As in most southern states, the *dosa* (fermented rice flour and lentil pancake) is common everywhere. However, the favorite remains *pesarattu*, a rice pancake with a filling of semolina and onions, cooked together. This is served with *sambar* (a spicy lentil preparation) and a variety of chutneys. Rice is a staple food in the region. No meal in Andhra is complete without the famous Andhra pickles that come in several varieties. *Rasam*, a spicy lentil soup, is common to the entire southern region, but interestingly, mulligatawny soup derives its name from the Telugu *mulligatanni* or black pepper water.

Hyderabadi food is distinct, having been influenced by renowned Moghlai cuisine. The kitchens of the Nizams combined the Muslim influence of the Moghlai court with a predominantly Hindu subculture to create a cuisine that is the ultimate in fine dining.

Hyderabadi cuisine includes *biriyani* (rice layered with mutton and cooked), *baleem* (wheat pounded with mutton), *baghare baigan* (roasted eggplant), and tomato *kut* (a tomato chutney). The repertoire is rich and vast, both in vegetarian and nonvegetarian fare. What also distinguishes Hyderabadi food is its sourness, clearly a Telugu influence. Souring enhances the taste of the food and is considered good for the heart and for digestion. The various souring agents used in Indian foods primarily reduce spoilage by microorganisms and also counteract the pungency resulting from the use of red or green chilies. The favorite souring agents are lemon and tamarind, although dishes like the *khormas* (meat curries with a creamy consistency) are soured with yogurt, and some dishes of Western origin, such as lamb chops, are soured with vinegar. Green mango when in season is a favorite

souring agent for meat dishes and dals. Another favorite is *narangi*, a sour citrus fruit, which is used to flavor various dishes. The tomato too is often used to sour a dish rather than as a vegetable. In Southern and Western India, *ambada* (roselle leaves), a kind of spinach with a distinct sour taste, is another great favorite. Fresh or dried prawns, chicken, or meat cooked with *ambada* can be quite delicious, as is common dal soured with *ambada*. Sour berries called *karonda* (*Carissa caranda*) and sour fruits such as *kamrak* (star fruit or carambola) are also used to sour meat dishes.

Hyderabadi food can, in addition, be hot and spicy, another Telugu influence. Specialties include several dishes that are picklelike in flavor: *chatni gosht* (chutney meat), *achar gosht* (pickle-meat curry), *achar ke aloo* (pickle-potato dish), and *mirchi ka salan* (picklelike dish of green peppers and special herbs).

Chili peppers are used in Hyderabadi cooking in several ways—they can be chopped, ground into paste, slit, and deseeded, or an entire chili can be inserted in the dish. Certain red chili powders, especially those that come from the coastal Andhra region, have a flaming red color and a hot taste.

The procedure of seasoning, or *baghar*, is used in Hyderabad to great effect in order to infuse a dramatic nuance of taste into a dish. In *baghar*, food is seasoned by a process of dropping chilies, herbs, and spices into hot oil and then pouring that concoction over a dish while it is still sizzling. There are also exotic methods of seasoning that are quite unique to Hyderabad. In a lentil curry called *thikri ki dal*, a piece of freshly fired earthen pot is broken, heated until red hot, and added to the dish so that the rich aromatic flavor of the earth is captured. Similarly, in a dish called *kabab kheema* (minced kebab), a piece of red-hot coal is deposited in the center of the cooking pan and covered immediately so that the kebab absorbs the smoke and flavor of the burning coal.

Certain spices that are hardly used in North Indian cuisines are rather commonly used in Hyderabad, quite obviously due to Muslim-Moghlay influence. These are *shah jeera* (black cumin), *khus khus* (poppy seeds), *magaz* (seeds of muskmelon and watermelon), and *kabab chini* (cassia buds). Another spice used very often in Hyderabad, a South Indian legacy, is *til* (sesame seeds), which is scarcely used in the North.

A magical mix of various herbs and spices called *bhojwar masala* is indeed a Hyderabad offering to Indian cuisine. It is used in dishes like *baghara baigan* (seasoned eggplant), *mirchi ka salan* (green chili curry), and *mahi gosht* (a meat dish), and contains a mixture of coriander seeds, sesame seeds, cumin seeds, bay leaf, groundnut, dried coconut, and a lichen with an exotic aroma curiously called *pathar ka phool* (stoneflower). Another mix of herbs and spices from Hyderabad and much more exotic is *potli ka masala*, thus named because herbs and spices are tied in a *potli*, a sack of muslin cloth, and placed in

Sugar is an important agricultural product from southern India, where it has been grown for several thousand years. This shows workers processing sugar in the open air. © ENZO & PAOLO RAGAZZINI/CORBIS.

the cooking dish. *Potli ka masala* is used mostly in *nehari*, a broth of pig's feet and goat's tongue, and *chakna*, a tavern dish of meat and organs. This mixture of spices is very different in taste and is literally an orchestra of fragrances. It includes sandalwood powder, dried vetiver roots, dried rose petals, bay leaves, coriander seeds, black cardamom, cassia buds, *pathar ka phool*, *gehunwala* (a kind of grain), *pan ki jadi* or *kulanjan* (a lesser variety of galin-gale), and *kapur kachri* (*Hedyllum spicatum*).

Hyderabadi cuisine is more nonvegetarian than vegetarian, but the repertoire of Hyderabadi vegetarian fare is also complex and indicative of a high level of cooking skill. Hyderabadi prefer rice to bread, although *phulka* and *paratha* are also eaten. An earthy Maharashtrian bread made from an Indian millet called *jawari ki roti* is very popular. Nonetheless, rice is overwhelmingly preferred. It is said that nearly forty varieties of *biryani* are made in Hyderabad, including *pulao*. In Hyderabad a delicious mixed-vegetable *biryani* called *tahiri* is often served. It is said that throwing a handful of it on the ground in a spray will test the quality of a cooked *biryani*. If each grain of rice falls separately from the other and the grains do not stick together, then the *biryani* has made the grade.

Hyderabad is also a curry paradise. Broadly speaking, Hyderabadi curries come in five to six forms. One is *shorva* (or *shorba*), a thin, soupy curry with dumplings of meat and a vegetable, which could be potato, okra, some of the gourds, or colocasia, and soured with tamarind and

## MIRCH KA SAALAN (WHOLE GREEN CHILIES IN A MASALA GRAVY)

*Mirch ka saalan* is among the better-known Hyderabad dishes. Since it keeps well for several days, the Hyderabadis often carry it with them on long road or rail journeys.

Preparation time	40 minutes
Cooking time	25 minutes
Serves	6–8 persons

### Ingredients

Green chilies, large	8–9 ounces, slit on one side
Onions	4, cut into 4–6 pieces each
Ginger	1-inch piece
Garlic	½ pod, with the skin removed
Coriander seeds	1 tablespoon
Cumin seeds	1 teaspoon
Sesame seeds	3 tablespoons
Peanuts	½ cup
Poppy seeds	1½ teaspoon
Dried coconut ( <i>copra</i> )	about 1 ounce
Fenugreek seeds	¼ teaspoon
Turmeric powder	¼ teaspoon
Red chili powder	1 teaspoon
Jaggery or sugar	1 teaspoon
Tamarind	2½ ounces
Curry leaves	a few
Cooking oil	1 cup
Salt	To taste

### Method

Soak tamarind in about 1 cup of warm water. Mash and sieve to obtain tamarind water. Discard seeds and other residues. Set aside.

Roast the onions on a griddle until they soften and turn a pale golden brown. Then dry-roast together over medium heat the coriander seeds, sesame seeds, peanuts, cumin seeds, poppy seeds, dried coconut (*copra*), and fenugreek seeds until their shade darkens very slightly and they start emitting an aroma.

Grind together the onions, roasted spices, ginger, garlic, salt, turmeric, red chili powder, and jaggery or sugar into a fine paste. Mix with the tamarind water.

Heat oil. Add the green chilies. As soon as they acquire a few golden brown spots, remove from the pan and set aside. Add curry leaves to the oil and, after a few seconds, the ground spices. Cook for about 5–10 minutes. Then add the green chilies. Cook over medium heat, stirring occasionally. Add a little water while cooking, if desired. Cook for another few minutes until the oil rises to the surface. The dish should have a fairly thick consistency.

a bit of yogurt. It is flaming red in color and can also be quite hot in taste as it is blended with red chili powder. Then there is *khorma*, which is a meat, chicken, or fish dish with a creamy consistency as it is flavored and soured with yogurt and spiced with red chili powder. All *khormas* are yogurt-based dishes. Then there are the thicker curries called *khalias*, which again are meat dishes with a vegetable in which the gravy is thick and saucelike. There are also the *bhuna* dishes, which are not exactly dry, as the name suggests, but have very little sauce, in which the mixture of spices coats the meat. Another group of curries without a specific name are those flavored with *baghar* or seasoning. In addition, there are some other curries outside these categories, but with a texture and flavor all their own.

Indians rarely bake their foods, except perhaps in the celebrated clay oven called the tandoor. Hyderabad, however, boasts of a few unique baked dishes, not surprisingly all made of minced meat. Most of these are actually *kabab*-like or are baked *kababs*, except perhaps the savory called *tootak*, made of semolina and minced meat. Some of the baked foods are obviously imports, from Arabian countries and Iran.

The gourmets of Hyderabad have incorporated other Arab dishes into their culinary repertoire, and the most spectacular of these is perhaps *muzbi*, in which an entire goat is stuffed with *pulao*, chicken, boiled eggs, and nuts and raisins, and then cooked. There is also *marag*, a rich broth of mutton and marrow, and the famous *nehari*, another fine broth of tongue and pig's feet. The Turks introduced Hyderabad to *shawarma*, slices of goat's meat upon a special skewer. All these dishes have been subjected to Hyderabad interpretation, and abundant use of unique Indian spices has imparted to them their own local flavor.

Another nonvegetarian category in which Hyderabad food offers tremendous variety and culinary excitement is minced meat. *Kheema* or minced meat has a certain versatility that allows it to be cooked in several ways. A mince dish is not supposed to be watery and therefore has very little gravy. However, it goes very well with rice or bread. Several *kababs* are made with mince, as are baked dishes and savories. Mince also lends itself well to stuffing. In a group of dishes called *dummay*, like the Greek and Armenian *dolma*, mince is stuffed in onion, potato, capsicum (sweet and hot peppers), and even fruits like apple and guava.

As in the West, there is a certain order in the manner in which food is taken in Hyderabad. Food is eaten in courses, but not served in courses. Everything is placed on the table at the same time, but eaten in a set order. A dry dish, generically called *gazak* (or appetizer), is first consumed. It could be a *kabab*, a savory, or even fried fish. The *gazak* is followed by *khalia*, a semidry mutton curry, which is eaten with *phulka* (a thin dry chapati). Then comes the *shorva* or *khorma*, which generally contains a vegetable. Alternatively, a *biryani* might be served

in place of the *shorva*. Similar order prevails in the presented food at weddings and parties, only the fare is more sumptuous and has greater variety. At parties and celebrations, at least two varieties of *gazak* and two types of *biryani* are served. A chicken dish and mutton curry are also offered to guests, along with bread. For dessert, favorites include *double ka meetha* (a bread pudding), called *shahi turka* in the North, and *khubbani ka meetha*, an apricot dessert served with fresh cream.

No introduction to Hyderbadi cuisine would be complete without a word on its pickles. Since the Indian passion is for foods sour and pungent, one predilection is pickles made of green mango, lemon, tamarind, green chili, and even sour fruits like the *kamrak* (star fruit). The pickles are all seasoned and flavored with vinegar.

The Hyderabadi *paan* (betel leaf) is well known. Making a good *paan* is a delicate process and is often an exercise in *nazakat* (elegance). The Hyderabadi prefer the South Indian leaf. It is soft and does not have the coarseness or pungency of some other leaves. Each leaf is fastidiously cleaned of all its veins in order to soften it further. Both the *katha* and *chuna* (slaked lime) are processed at home. The *katha* is also treated with rose water. At the end of a meal, a silver *paandaan* (a container for the betel leaf preparation) is brought out and the lady of the house makes the *paan* with her own hands. The *paan* is rarely given by hand. It is placed in a miniature silver tray and offered with the right hand. (Food in Indian homes is always served and eaten with the right hand. The left hand is not used for either purpose, for traditionally the practice in Hindu homes is that the right hand is used to receive and/or give.) At parties, *paans* are decorated with *chandi ka varq* (silver leaf) before being served.

Andhra cuisine is largely vegetarian, except for the coastal areas, which show a preference for seafood. Fish and prawns are curried in sesame and coconut oils, flavored with freshly ground black pepper, and then eaten with rice. For vegetarians, rice is served with *sambar* (a spicy lentil preparation) and vegetables. *Pakodas* (potatoes or onions dipped in gram flour batter and deep-fried), *vadas* (fried dumplings made from split black gram) in steaming hot *sambar*, or *idlis* (steamed rice dumplings) are served as snacks. The Portuguese word for grain, *grão*, was first applied in India to the Bengal gram or chickpea, and later applied generally to all pulses; thus arose the terms red gram, green gram, black gram, horsegram, etc. Gram's use is unknown outside India.

A wide variety of fruit grows in Andhra Pradesh. These include custard apples (*Anomas*), grapes, apricots, and mangoes.

## Karnataka

Writings on food in Kannada date back approximately a thousand years. Rice was the premier food after the tenth century C.E. in Karnataka. Four varieties of a cooked rice-

A traditional Thali tray in Madras, India. Each bowl contains a small portion of a vegetarian dish. © LINDSAY HEBBERD/CORBIS.

ghee combination dish flavored with garlic and salt, called *kattogara*, were prevalent. Crushed *papads* was added to yield one variation, crisp-fried *sandiges*, made of the ash gourd made for another, and various cooked greens gave rise to yet other variations. By mixing in lime, *huli* (a spicy lentil preparation), turmeric, tamarind, or the powders of roasted rice and split chickpeas, flavors could be easily changed. Cooking the rice in water in which, as a preliminary step, the leaves of *tulasi* (holy basil) were boiled resulted in "curd rice" (a traditional preparation) that would keep for several days.

An exceptionally large number of wheat preparations also continue to be consumed. Karnataka consumes roughly equal amounts of rice, wheat, and *ragi* (millet). The wheat foods may be roasted, baked, steamed, or fried. Roasting can take several forms. *Mucchal roti* is baked between plates, with live coal above and below, and *kivichu roti* on a *kavali* or *tava* (flat griddle plate) with a little ghee (clarified butter). Several *tava*-roasted rotis may be mounted one over the other with a pierced stick and flavored with ghee, sugar, edible camphor, and *thale* (*Palmyra*) flower to yield *chucchuroti*. A stack of ghee-smearing circles mounted one over the other, *savaduroti*, is baked on a griddle under cover of a cup. A cup cover above, live coals below, and a ball of dough within yield *uduru roti*, from which the blackened crust is peeled off before consumption. *Mandige* or *mandage* is a delicate baked product: when baked on a heated tile, it is called *white mandige*, and when overheated but still very soft, it is called *ushnavarta mandige*. The stuffing may be varied. Sugar and ghee yield *khanda mandige*; multilayered fillings of cooked *chana*, coconut shreds, dates, and raisins result in a *mandige* variation called *perane hurige*. Today the *mandige* of Belgaum is a very large and fine *paratha* stuffed with finely ground sugar containing cardamom powder, baked on an upturned clay pot, and folded into a moderately stiff rectangle.

True baking within a seal of wheat dough, called *kanika* in Kannada, is used to make the *bhojanadbika roti*, in which *mandige* broken up into small pieces is mixed with milk, cream, coconut milk, mango juice, and sugar, and then pressed into a ball. This is placed within a covering of wheat dough and baked under seal on a hot tile with frequent turning of the vessel. When done, the upper crust is sliced off, and ghee and sugar are poured on the *roti* before it is consumed.

Wheat dough made with sweetened milk or even cream, rolled out into circles and then deep-fried, yields *yeriappa* and *babara*. Balls of dough made with wheat flour, curds, and sweetened cream are deep-fried to produce *pavuda*. A less viscous wheat batter prepared with sweetened milk is forced through a hole made at the base of a coconut shell cup (the usual extrusion device) directly into hot ghee for ropelike *chilumuri*.

Some preparations have been frequently mentioned throughout the centuries. *Melogara* is a dish of pulses and greens, with coconut gratings, but many variations are prevalent. To make it, *mung dal* (split green gram), *avarai* (flat beans), *urad dal* (split black gram), fresh *chana* (split chickpeas), or *tuvar dal* (split red gram) are first cooked with sesame seeds, then cooked again with greens, drumsticks, grapefruit, salt, and coconut gratings, and finally mixed with ghee and tempered with asafetida (gum resin) and thick milk. Even wheat dough pieces rolled into thin strands and fried may be added to *melogara*. Vegetables used for *melogara* are pretreated. Certain leaves are first washed in lime water before cooking, other greens are washed in turmeric water, and yet others with common salt or alkaline ashes. The *surana* root is first boiled with betel leaves, or soaked in rice water and then cooked with tamarind leaves. A *melogara* of dal and beans may be sweet, sour, or spicy.

There are many kinds of relish in this cuisine. *Balaka* is now made by soaking large chilies in salt water, drying them, and then frying the chilies in oil when needed as a crisp and spicy accompaniment to food. Historically, some twenty kinds of *balaka* have been prepared using various vegetables and their peels. Deep-fried items eaten as crisp and crunchy accompaniments to a meal include *chakkali* (called *murukku* in Tamil Nadu), a circular mass of continually widening rings extruded from a thick rice-*urad* (split black gram) batter, and numerous *sandige*, irregular lumps of spiced rice-*urad* batter, sesame powder, onion, or even vegetable skins like those of the ashgourd, sun-dried first, and then deep-fried until crisp in very hot oil. Curd-based relishes with greens and raw vegetables are called by various names, such as *pacchadi*, *kacchadi*, *krasara kacchadi* (this contains milk with curds), *palidya* (one variety is called *kajja*), *thambuli* (with greens and coconut gratings), and *raita* (a commonly used condiment today). *Kosamris* are uncooked relishes made from *chana* or mungbean sprouts (green gram), which are soaked in water until they soften and swell, and then garnished with salt, mustard seeds, and fresh coriander.

In the cuisine of Karnataka, there has been a vast variety of sweet items, and they have altered little over a millennium. Sweet boiled rice, rice *payasam* (rice cooked in milk and then sweetened), rice-derived *vermicelli payasam* (vermicelli pasta cooked in milk and sweetened), mixed *rice-wheat payasam* (a mixture of rice and wheat cooked in milk and sweetened), *rice kadabu* with a sweet filling, and deep-fried delicacies of rice flour and jaggery (now called *athirasa*) are all based on rice. Wheat, especially in the form of semolina, is suitable for the preparation of sweets; from it, *kesari bhath* (sweetened rice flavored with saffron), *ghrtapura* (a fried ball), *payasam* (*kajjaya*), and *ladduge* are made. Wheat vermicelli is extruded to a fine consistency from hard wheat dough (it is then known as *pheni*) and usually eaten with sugared milk. Sweet wheat rotis stuffed with a mash of boiled *chana*, jaggery (brown palm sap sugar), and coconut constitute *purige*, *burige*, or the later *holige*; a thinner drier form is *obattu*, and there is also the rolled-up cylindrical form called *surali holige*. Rolled-out pieces of dough are fried in various forms and then dusted with castor sugar to make *phenis* and *chirotti*; *madbunala* is a small tube of dough (of wheat, rice, and *chana* with added mashed banana) filled with sugar, sealed at both ends, and then deep-fried. *Karaji kayi* is a half-moon puff with a sweet stuffing; if only sugar constitutes the stuffing, the result is *sakkare burunde*. Pulse flours of *chana* and black gram are also used to make sweetmeats. *Boondi* grains made from them are sweetened with sugar syrup and shaped into *ladduge*, *pinda*, *moti chur*, and *manohara unde*. *Jilabi*, tasty as nectar, are made of *chana* flour. Milk is the major ingredient for sweet *payasa*, as well as *bal unde* (balls of sweetened milk solids) and *balaugu*. *Shikharini* consists of curd solids lightly spiced and sweetened.

A typical breakfast in the region includes *idli* (made by fermenting a mixture of ground rice and split black gram) and *vada* (made from split black gram), accompanied by *sambar* (a spicy lentil preparation) and a coconut chutney, lemon rice, *upitu* (a savory dish made from semolina), or *kesari bhath* (a sweet made from semolina and flavored with saffron).

*Vermicelli upma* (a savory dish made with vermicelli pasta) is used as a snack in-between meals. The main meals are usually rice-based. Rice is eaten with clarified butter. This is followed by rice with *rasam* (a thin lentil soup), rice with *sambar*, and rice with curds for the final course. Usually, two vegetables called *palyas* accompany the meal. These are dry-cooked vegetables with green chilies, cumin, and grated coconut. A salad called *kosamri* is also eaten with the meal.

The Kodavas, Mangaloreans, and Udupis are distinct communities within the state; each has its own specialties.

Perched on the highlands of southern Karnataka in the Kodagu district are a warlike and distinctive people with a unique cuisine. Rice is eaten boiled or as a distinctive ghee-coated product (*nai kulu*), or as a *pulao* with

firm meat chunks and every grain coated evenly with a mixture of spices. Rice is also transformed in numerous ways, and each has a distinct nonvegetarian accompaniment. The *akkiroti* based on a rice dough rolled out on a wet cloth is roasted and eaten with a spicy sesame chutney, a red pumpkin (*kumbla*) curry, or with a dry and salty dish of bamboo shoot chiplets (these shoots are also pickled).

With the *pulao* goes a tasty relish of ripe wild mangoes in a curd base called *mangay pajji*. A paper-thin, soft rice pancake, *neer dosai*, is accompanied by a chicken curry, into which a lot of fresh coconut is added. The *nu puttu* of Kodagu is the strandlike *idi appam* of South India, once eaten with jaggery water, but now with any liquid curry. Steamed balls of cooked and mashed rice constitute *kadambuttu*, which is paired with a pork dish with a very thick mixture of spices, of which an essential ingredient is the sun-drawn extract of the kokum fruit, locally called *kachampuli* (*kerala kudampuli garcunia cambogia*). Its acidity serves to keep the fat on meat firm and springy. A breakfast dish, *paputtu*, is prepared from rice grits mixed with grated coconut and milk, and then steamed in metal pans. This is often eaten with either pork curry or ghee and the honey so plentifully found in Kodagu. Another breakfast dish is *thaliya puttu*, made from a batter of ground rice, fenugreek seeds, and soda bicarbonate, fermented overnight and steamed. Two fish are commonly used in this cuisine. One is the sardine, *matthi meen*, and the other the tiny whitebait (*koyle meen*), cooked and eaten bones and all. There are also two popular desserts and both are based on the banana. Well-ripened fruits are mashed with the powder of roasted rice, to which a little fenugreek is added, to make uncooked *thambuttu*, which is eaten with ghee, fresh coconut gratings, and whole-roasted sesame seeds. To make *koale puttu*, mashed banana and small wedges of mature coconut are steamed in a banana leaf packet, which is opened to give a brown slab; the mixture is then eaten either hot or cold with fresh butter. The name is derived from *koovale puttu*, originally made with the soft, weepy variety of jackfruit called *koovale*.

### Tamil Nadu

Located in the South of India on its Eastern coast, Tamil Nadu has a large Hindu population. The large community of Brahmins are vegetarian, hence, the state is primarily vegetarian by nature. The main cooking method in the South is steaming. As a result of this, every single home is equipped with a variety of small and large steaming pots. The word "curry" originated in Tamil Nadu. Contrary to popular belief that a curry is a dish with a gravy, curries in Tamil Nadu are dry, spiced dishes without gravy.

Most of the south, and particularly Tamil Nadu, has a hot climate, and this has been used to prepare some of the most delicious and nutritious dishes that require fermentation. For this process, no yeast is used, as the

### THE UDIPIS

The Udipi region is on the coastal stretch of Karnataka, sandwiched between Goa and Kerala. The Krishna temple in the area is famous for training young boys (from the age of ten years) to work in the kitchen. All boys start as apprentices and gradually learn the trade. Thereafter, they are free to seek employment elsewhere. This has given rise to a whole chain of "Udipi restaurants" throughout Maharashtra and Karnataka. The food served at any of these places is completely standardized, with each item having the same weight, volume, and appearance. Long before the concept of chain restaurants came about in the West, along with the accompanying standardization of foods, the ubiquitous Udipi restaurant was already making its presence felt in India!

### THE MANGALOREANS

The Christian community of Mangaloreans are an integral part of Karnataka. However, their food is quite different from Hindu cuisine, being as nonvegetarian as the Hindus are vegetarian. In fact, it has several similarities with the coastal cuisine of Kerala: both make use of coconut milk and similar spices. Seafood, being readily available, is also consumed in large quantities, as is heavily spiced pork.

average temperature of 25°C does the work quite effortlessly. To counteract the heat, cooling ingredients such as tamarind are employed to great effect.

*Idlis*, small, savory rice cakes, made slightly sour by overnight fermentation and steamed the following morning, are served as breakfast to millions in the South. The process relies almost entirely on the weather to change a batter of ground rice and split peas into a light froth, which then only requires a quick steaming to become a deliciously light, highly nutritious, and very digestible breakfast.

South Indians are serious coffee drinkers. They make strong filter coffee, but do not drink it strong, preferring to mix it with lots of hot milk. The proportions vary from house to house. Sometimes, as little as 20 percent coffee is in an individual serving, and at other times it is a neat balance of half and half. Before the coffee is poured into separate glasses or cups, there is one more ritual to be performed: that of pouring the mixture from one vessel to another at some height in order to raise a head of froth.

### ACHAR KE ALOO (POTATOES IN A PICKLE SAUCE)

Preparation time	15 minutes
Cooking time	45 minutes
Serves	6–8 persons

#### Ingredients

Potatoes	1½–2 pounds
Onions	5, ground to a paste
Ginger paste	1½ teaspoon
Garlic paste	1½ teaspoon
Red chili powder	1½ teaspoon
Turmeric powder	1½ teaspoon
Vinegar	1/3 cup
Sugar	2 teaspoons
Salt	To taste

#### For tempering

Nigella seeds	1 teaspoon
Mustard seeds	½ teaspoon
Cumin seeds	1 teaspoon
Whole red chilies	8

#### Method

Boil the potatoes. Peel and cut into 1-inch-sized pieces

Heat oil. Fry the potatoes until they are golden. Set aside. Leave about 2/3 cup of oil and remove the rest. Next fry the onions until they are golden brown. Add the ginger and garlic paste and fry a little. Next add salt, turmeric, and chili powder, and then the fried potatoes. Add about half a cup of water and cook over low heat for approximately 5 minutes until the spices are well blended and a small amount of gravy remains. Turn off the heat. Mix sugar in vinegar and add to the dish. Transfer all to the serving dish.

Heat 2 tablespoons of oil. Add the dry whole red chilies, mustard seeds, cumin seeds, and finally the nigella seeds. When the mustard seeds begin to crackle and the red chilies darken, pour the tempering over the dish.

tially cooked bread is held over an open flame for a few seconds. The direct heat causes moisture in the dough to turn quickly to steam, puffing the bread while the cooking is completed. For a crisper effect, unleavened dough may be cooked completely on the griddle until well browned on both sides.

The main staple in Tamil Nadu is rice. Simple vegetarian lunches consist of three courses, each eaten with rice. A typical lunch menu would be rice and *rasam* (a highly spiced lentil soup) and a preparation made from vegetables. This is followed by more rice for the second course, with *sambar* (a preparation of lentils) and *pa-padams*. The last course comprises rice, yogurt, and pickles. Southern meals tend to end this way: hot, fiery courses followed by bland, soothing ones.

Vegetarian meals using the same basic theme of rice, *rasam*, *sambar*, and yogurt may in skillful hands become much more elegant and elaborate. Examples include *rasavangi*, a kind of heady *sambar* with the tiniest of eggplants (aubergines) bobbing about in it; *vendakai curry*, delightfully crisp fritters made by dipping sections of okra into a spicy chickpea flour batter and frying them; *keerai poricha kootu*, a kind of thick soupy stew of lentils, spinach, and fresh coconut; and the popular *rasavade*, made with savory *urad dal* (split black gram) doughnuts, immersed in *rasam* just long enough to soften and soak up all the liquid's tart and fiery flavor.

#### Chettinad

Traders, merchants, and money-lenders by profession, the Chettiyars of Chettinad have traveled the seas freely since ancient times. Their wealth is enormous, and the Chettiyars are very comfortable with and open about this. They are known to begin collecting dowries for their daughters at birth. The Chettinad region of southern India that comprises Madurai, Virudhunagar, and adjoining regions is dry and arid. The cuisine of the region reflects this and also the fact that the early Chettiyars were traders in spices. Therefore, their cuisine is spicy (fiery hot) and rich in its variety of spices, the most prominent being peppercorn and red chilies.

In Chettinad a meal is traditionally eaten off a banana leaf. Some popular preparations are *meen varuval*, fried fish; *varuval kola*, fried meatballs made with a very creamy paste of meat, cashews, poppy seeds, coconut, fennel, and fenugreek seeds; *koli kolambu*, chicken cooked in spicy tamarind water; *kari kolambu*, meat cooked with roasted coriander seed and tomatoes. There are also dishes made from mixed vegetables cooked with the second water used for washing rice (*mandi*) or *idi appams*, freshly made rice vermicelli, seasoned with mustard seeds and *urad dal* (split black gram), as well as dishes made from banana flowers, banana stems, dried mango, and assorted pickles and sweets. Fennel and roasted and powdered fenugreek are the predominant spices in Chettinad chicken, fish, and vegetable preparations.

A *dosa* is more satisfying than a simple pancake, as it is golden red and crisp on one side, smooth and white on the other. Made from almost the same batter, both *idlis* and *dosas* are the traditional breads of the South, as nourishing and digestible (due to the fermentation process) as they are delicious. They may be eaten with butter and honey or with chutneys, or they may be stuffed with a spicy blend of potatoes and onions. All these breads are unleavened and prepared in two stages. First, each round is cooked briefly on a preheated griddle; then, the par-

*Koli uppu varuval*, a kind of peppered fried chicken, is a dish that has gained immense popularity outside the Chettinad region.

## Kerala

Kerala is a bit of heaven on earth. Located as it is on the West coast of India, with a long coastline, the food of the state has been influenced greatly by its climate and geographic location. There is a wealth of seafood, and the swaying coconut palms all along the coastline have resulted in the extensive use of coconut and coconut oil in the local cuisine. Other foods locally produced and consumed include many types of bananas and jackfruit. Kerala is well known for its spices. In fact, the Greeks, Romans, Arabs, and Chinese all came to Kerala to trade. Later, Portuguese, Dutch, French, and English explorers arrived to profit from the lucrative spice trade.

Black pepper is the main spice grown in Kerala. It was used in the past as currency, to pay tributes and ransoms. Other spices that grow in the area include nutmeg, cinnamon, cardamom, cloves, ginger, and turmeric. Tamarind trees and the curry leaf tree (*Murraya koenigii*) are visible everywhere; the aromatic curry leaf has greatly influenced the cuisine of the Keralites as a result. Kerala also produces large amounts of coffee and tea, and manicured tea gardens can be seen on the hills of the region. There are three major communities residing in Kerala. Hindus, Muslims, and Syrian Christians make up the bulk of the population of the state, although there are other minority communities, including Jews.

Each community has its own distinctive cuisine. Unlike the royal families of other states such as Hyderabad and Mysore, those of both Travancore and the state of Cochin are extremely austere and spartan in their food habits and lifestyle, although they are great scholars and lovers of art. Other states were known for their opulence, both in lifestyle and cuisine, but this is lacking among the royal families of Kerala. However, during the Onam festival, all Keralites enjoy a festive meal. Nonetheless, there is no special cuisine that can be attributed to them.

**The Syrian Christians.** Breakfast for all Keralites, whatever their religion, is the popular *appam* (also called *hoppers*), a pancake, or *palappam*. These are rice flour pancakes, which have soft, thick spongy centers and lace-like, thin, crisp edges. The Syrian Christians eat *palappam* with a meat stew, whereas the Hindu community comprising the Nampoothiris and Nairs eat it with a mix of vegetables (*aviyal*).

There are two other breakfast items common to all Keralites. The first is *idiappam* (cooked rice noodles or string *hoppers*), eaten with sweetened coconut milk or with a meat or chicken curry. The second is *puttu* (made of coarsely ground rice flour and coconut shreds, which are alternately layered in a bamboo tube, and steamed by affixing the bamboo tube to the mouth of a vessel containing boiling water). Being rather dry, *puttu* is com-

monly eaten with bananas or with a spicy dry chickpea curry.

*Kuzhal appam* is a fried crisp curled up like a tube; it is typically Syrian Christian. There are two other *appams* popular with this group, and both are sweet. *Acchappam* is a deep-fried rose cookie made of rice, the name derived from the frame (*acchu*) needed to make it. *Naiappam*, called *athirasam* in Tamil Nadu, is a deep-fried, chewy, dark doughnut fashioned from toddy (fresh or fermented palm sap), fermented rice, and jaggery.

Another rice-coconut combination uses fried rice and is called *avilose*, a Syrian Christian speciality. It can be molded into an *unda* (ball) with coconut palm treacle. *Churuttu* (which literally means cigar) is also rice-based; it has a crisp, translucent outer case, filled with *avilose* and coconut palm treacle. *Khumbilappam*, eaten by all Keralites, consists of a mash of ripe jackfruit, roasted rice flour, and jaggery, folded in the form of a triangle in a cassia leaf and steamed. During jackfruit season, a preserve called *chakka varattiyathu* is made with jackfruit, jaggery, and cardamom. This preserve is served continuously throughout jackfruit season.

Syrian Christians in Kerala eat beef, and *eracchi olarthiyuthu* (fried meat) is a daily food item, which is also served during weddings. It is a dry dish of cubed beef boiled with spices and pieces of coconut and then sautéed in oil. *Kappa kari*, pieces of tapioca cooked with ground coconut and tempered with oil, is another favorite dish among this community. Most curries, including meat, always have a lot of coconut milk.

In Kottayam and Trichur, both sea and river fish distinguish local fare. In Kottayam, the fish is cooked using a sour fruit rind (*Garcinia cambogia*), locally called *kudampuli*. *Meen vevichathu*, fish in a fiery red chili sauce, has a characteristic sour and smoky flavor, resulting from the *kudampuli*.

In Trichur, tender mango is the souring agent used along with coconut milk. *Meen pattichadhu* includes very small fishlike oil sardines, or even prawns with coconut gratings. A hot favorite with the laity and priests alike is *mappas*, a mildly spiced chicken curry with a thin coconut gravy.

A special sweet traditionally served at weddings is *thayirum pazham pani*, coconut palm treacle, which is poured on ripe bananas, mashed together, and then eaten with curd and rice.

**The Muslims.** The Muslims of Kerala are called *moplahs*; they are direct descendants of Arab traders who married local Kerala women. Although the Kerala freely use rice, coconut, and jaggery, an Arab influence may be clearly observed in their *biriyanis* and a ground wheat-and-meat porridge, called *aleesa*, elsewhere referred to as *harisa*.

The Muslim kind of *roti* is the distinctive *podi patthiri*, a flat thin rice chapati made from a boiled mash of rice,

baked on a *tava* (flat griddle plate), and dipped in coconut milk. *Aripatthiri* is a thicker version of this made from parboiled rice and flattened out on a cloth or banana leaf to prevent it from sticking. *Naipatthiri* is a deep-fried *puri* of raw rice powder with some coconut, fried to a golden brown. All these *patthiris* are eaten at breakfast with a mutton curry. Steamed *puttus*, eaten with small bananas, are also commonly consumed as the morning repast. A wedding-eve feast may include *nai choru*, rice fried lightly in ghee with onions, cloves, cinnamon, and cardamom to taste, and finally boiled to a finish. A wedding dinner generally includes a *biriyani* of mutton, chicken, fish, or prawns that is finished by arranging the separately prepared flesh and the cooked rice in layers and then baking them with live coals above and below. Several flavored soups are made from both rice and wheat, with added coconut or coconut milk, and spices. A whole-wheat porridge with minced mutton cooked in coconut milk is called *kiskiya*. A distinctive and unusual sweet is *mutta mala* (egg garlands), chainlike strings of egg yolk cooked in sugar syrup but later removed from it. *Mutta mala* is frequently served with a snowlike pudding called *pinnanthappam* made from the separated egg whites that have been whisked up with the remaining sugar syrup, steamed, and then cut into diamond shapes. This dish is indicative of the Portuguese influence in the area.

**The Hindus.** There are three main communities within the Hindu group, each with its own distinct cuisine: the Thiyas, Nairs, and Nampoothiris.

The Thiyas are a community that formerly tapped palm sap, but have now entered many other professions. *Appam* and stew are typical breakfast fare, the stew being varied: fish in coconut sauce with tiny pieces of mango, mutton in coconut milk, or simply a sugared thick coconut milk. A specialty bread is *naipattbal*, in the shape of a starfish. The curd of favor is *pacchadi* (a dish made of beaten curd with cooked vegetable marrow and coconut ground with mustard seeds, and then tempered again with mustard seeds and oil). A popular dessert is *prathamam*, split green gram boiled in coconut milk and flavored with palm jaggery, cardamom, and ginger powder, and laced with fried cashews, raisins, and coconut chips.

The *Nairs* were the original warrior class of Kerala, whose cooking skills later led to their employment as professional chefs to nonvegetarian families all over the South. Breakfast typically consists of *palappam* or bamboo-steamed *puttu*, eaten with sweetened milk and tiny bananas. Certain vegetable specialties, although eaten by all Keralites, have special Nair associations. *Aviyal* is a mixture of green bananas, drumsticks, various beans, and green cashews (distinct to Nair cuisine), cooked with ground coconut and a little sour curd, and then topped with some coconut oil. *Kalan* is similar, but uses green bananas alone, with a gravy of yogurt, ground coconut, cumin, and green chilies. *Olan* is a dish of white pumpkin and dried beans cooked in coconut milk; fresh co-

conut oil is poured on top of it after the cooking pot is removed from the fire. A Nair wedding feast will generally include several types of *pacchadis*, pickles, chips, and *payasams* based on milk, coconut milk, rice, dal, and fried vermicelli. No meat is served at a wedding, although it is part of the typical diet. Such domestic meat and chicken dishes, although spiced, use a great deal of fresh coconut and coconut milk for tempering. A yogurt dish containing small pieces of ash gourd or raw mango cooked with coconut, curds, and chili paste is called *pulisseri*. A sweet mango chutneylike dish called *puli inju* (fried sliced ginger in a tamarind chili jaggery sauce) is served daily.

The *Nampoothiris* are the Brahmins of Kerala who probably first arrived there around the third century B.C.E. They are strict vegetarians who favor the *idli*, *dosai*, and *puttu* for breakfast with a coconut or curd accompaniment, and eat their rice with *kootu* (a preparation of mixed vegetables), *kalan*, and *olan*. The use of garlic in cooking is avoided. Other vegetable preparations consumed include *thoran*, which is usually made from runner beans, sliced fine and then steamed and tossed with grated coconut, ground turmeric, cumin, and green chilies and tempered with oil. Other bean varieties such as field beans, sword beans, green bananas, amaranthus, cabbage, and peas can all be made into *thoran* and eaten with rice. *Aviyal* and *erusseri*, a pumpkin curry, are also included in the Nampoothiri menu.

All Keralites eat yellow banana chips fried in coconut oil and lightly salted. The *payasam* of Kerala is made with rice and milk, but *prathamans* use milk, dried fruit, and dal or paper-thin shreds of a rice roll, which are then pre-cooked and added to the sweetened milk to yield *palada prathamam*. Memorial services held once a year for ancestors routinely include *chattha pulisseri* in their menu. This is a sour buttermilk preparation with pepper, salt, and coconut paste that is thickened through boiling.

**INDUS VALLEY.** The food on which the diverse peoples of ancient India lived is a subject that has received some attention since archaeologists can recover bones, teeth, and carbonized seeds from their excavations. The period covered in this entry has come to be called the Indus Age (Possehl, 1999), that period in Pakistan and northwestern India which stretches from the beginnings of farming and herding around 7000 B.C.E. through the Early Iron Age to about 500 B.C.E. This period encompasses the Indus Civilization (2500–1900 B.C.E.), the Indian subcontinent's first period of urbanization (Fig. 1).

It was centered on the Indus Valley and the Punjab, but there were important settlements in southern Baluchistan, Gujarat, northern Rajasthan, Haryana, and western Uttar Pradesh (Fig. 2).

From the point of view of soil, water, and climate, these are regions suitable for the growing of wheat and barley and the raising of cattle, sheep, and goats on a significant scale. This is the constellation of plants and animals on which the earliest farmers and herders thrived, from the Mediterranean Sea to the lands of the Indus civilization.

A glimpse at an early period of farming and herding in this region is available from the site of Mehrgarh, on the Kachi plain of the Indus Valley. Around 7000 B.C.E., the inhabitants of this village lived mostly on domesticated, naked six-row barley, along with two other varieties of domesticated barley. Einkorn, emmer, and hard wheat were present in smaller amounts. The noncereals include the Indian jujube, a cherry-sized fruit; grapes; and dates. Sugar would have come from honey.

The use of domesticated rice by the peoples of the Indus civilization is not fully documented. However, by the second millennium B.C.E., it was the staple food grain at the site of Pirak, near Mehrgarh on the Kachi plain.

The animal economy of early Mehrgarh was dominated by twelve species of what can be termed “wild big game”: gazelle, swamp deer, nilgai, blackbuck, onager,

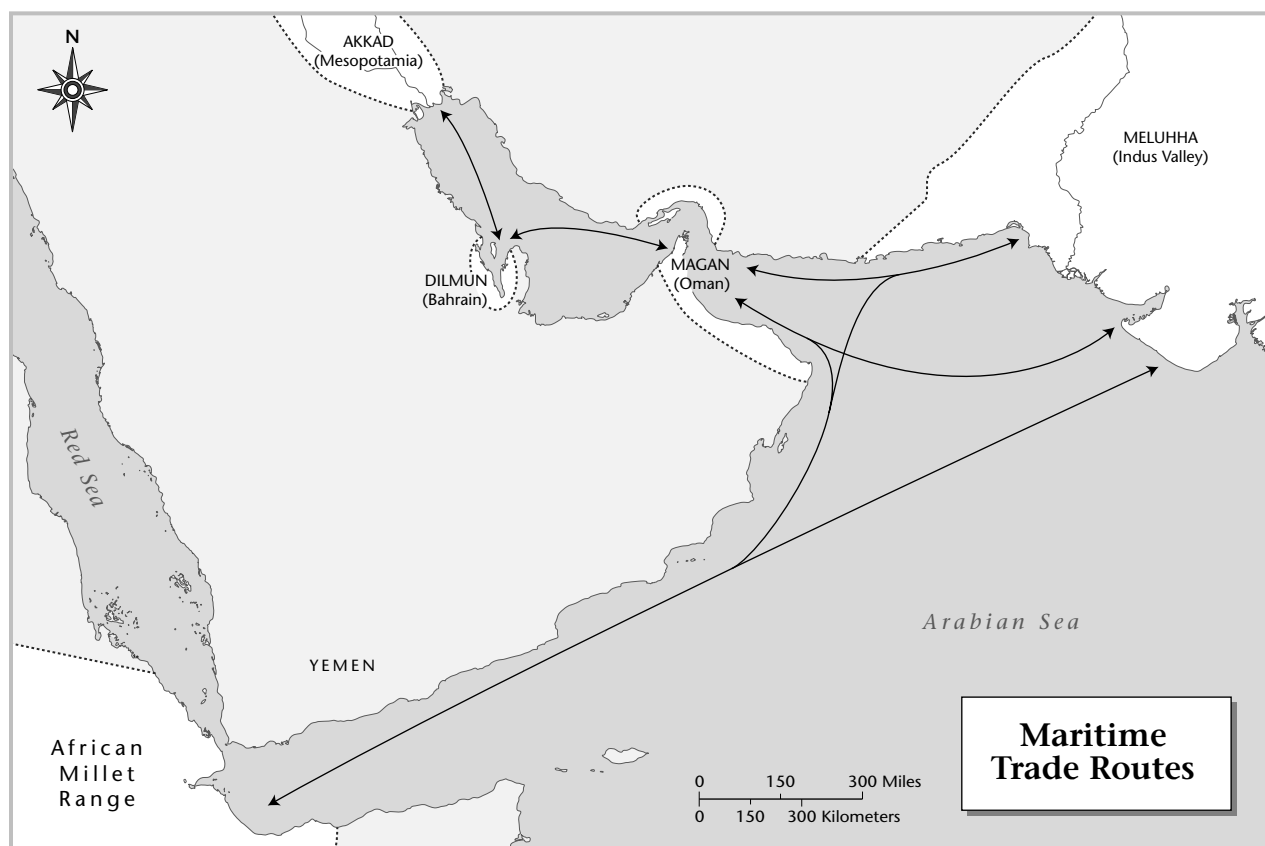

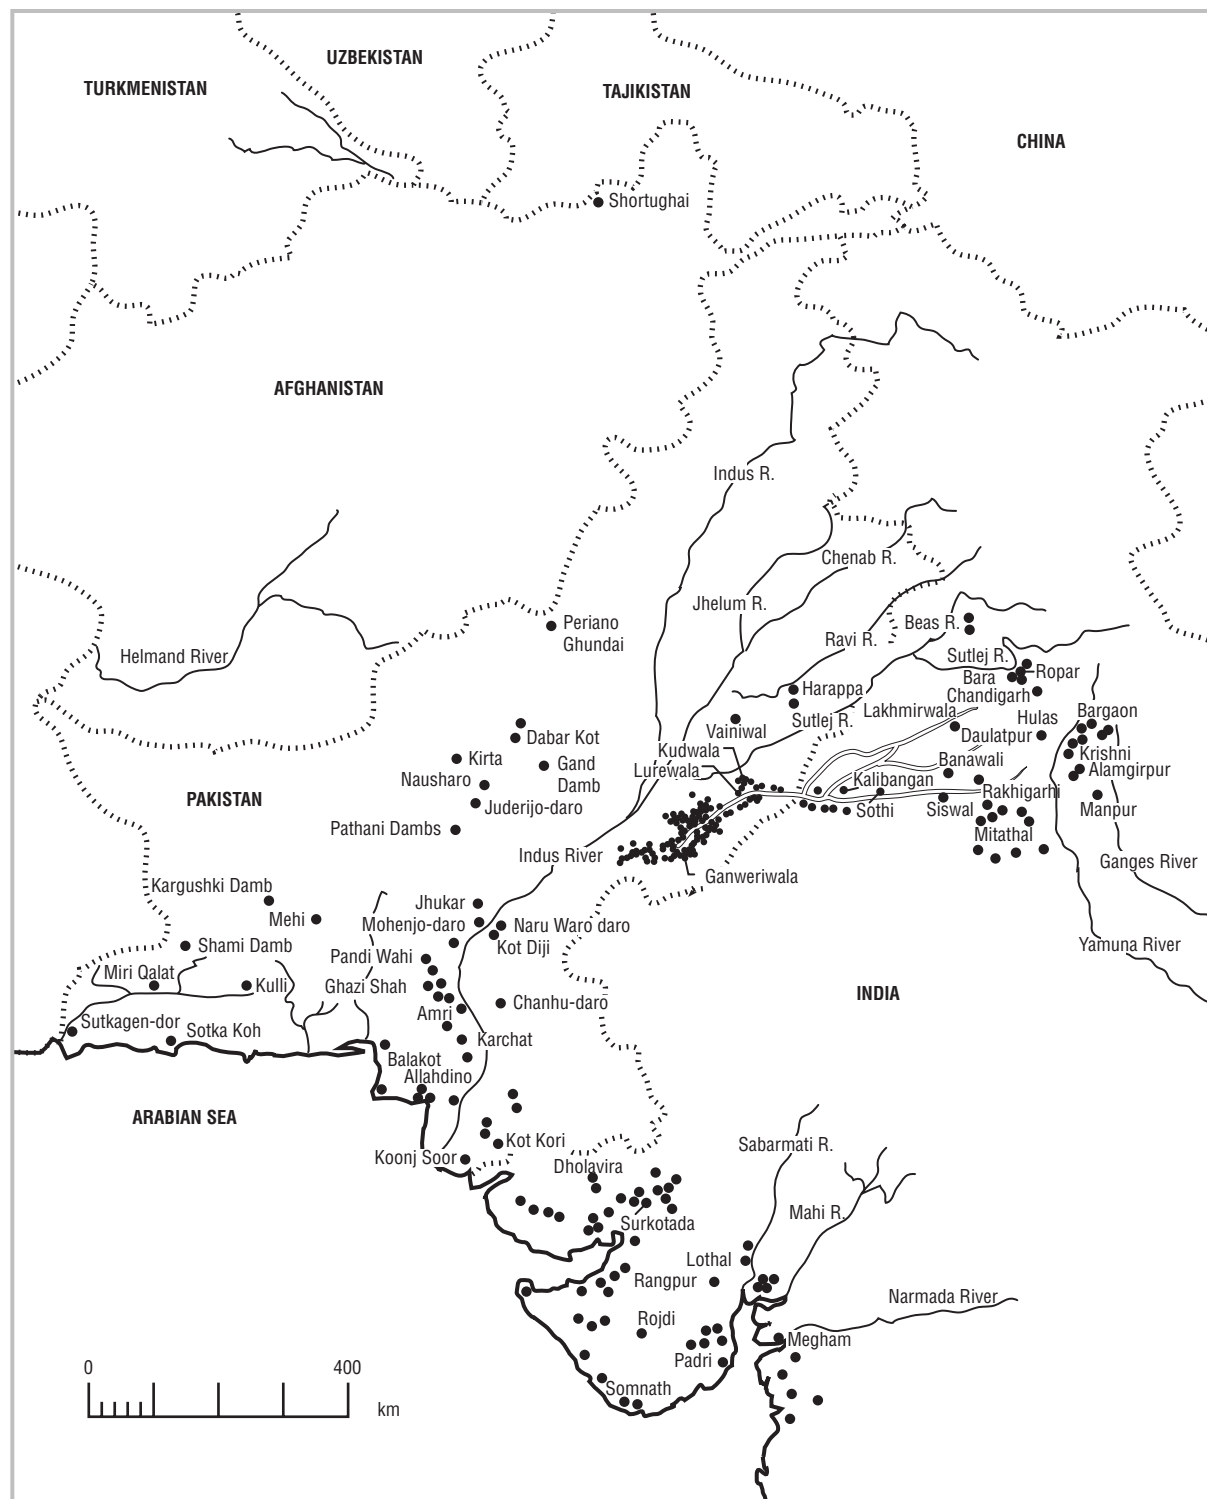

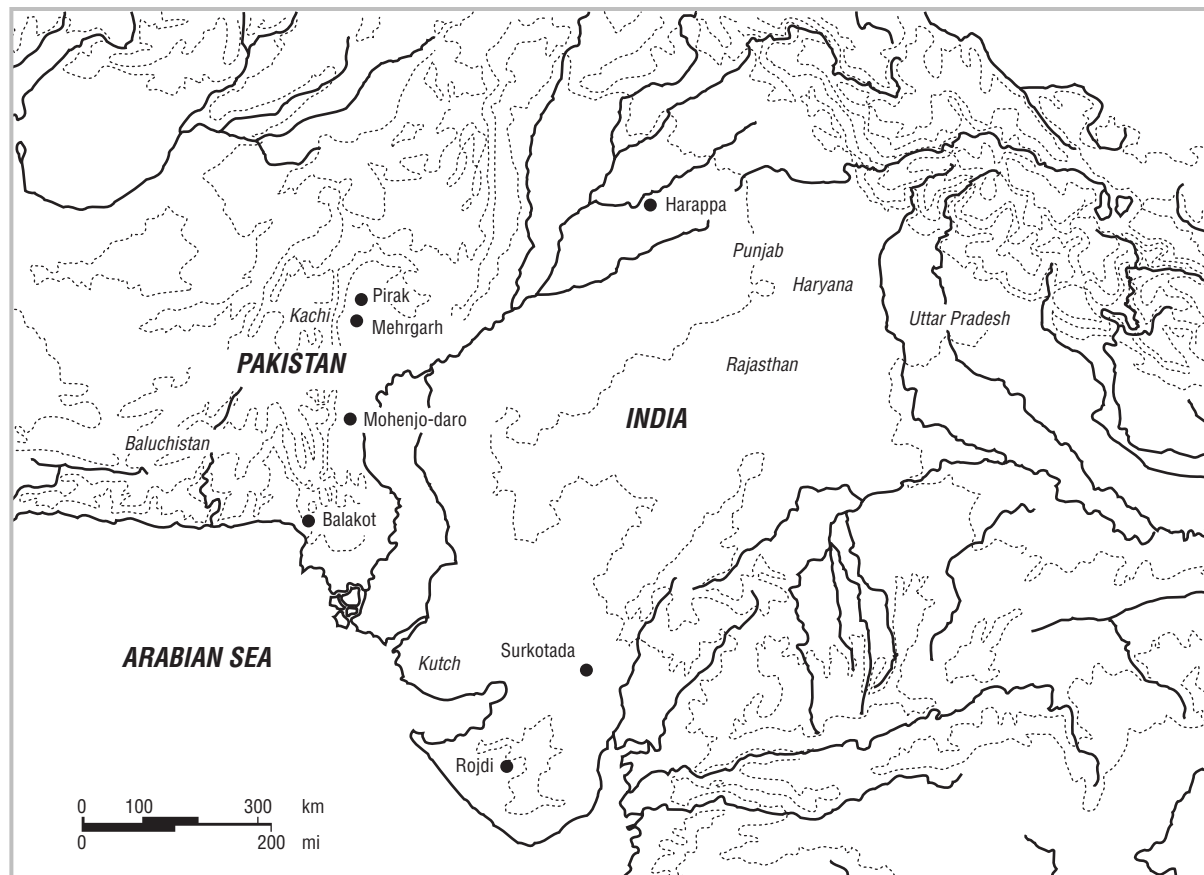

FIGURE 1

spotted deer, water buffalo, sheep, goat, cattle, pig, and elephant. These are animals that would have lived on the Kachi plain itself and the hills that surround it. The virtual absence of fish and bird remains suggests that the

swampy environments near Mehrgarh were little exploited, but no screening was undertaken at the Mehrgarh site, and the recovery of fish and bird bone was therefore somewhat compromised.

FIGURE 2

Meadow has noted the following concerning the subsistence economy of early Mehrgarh:

1. Goats were kept from the time of the first occupation of the site.
2. Cattle and sheep are likely to have been domesticated from local wild stock during Periods I and II (c. 7000–5000 B.C.E.).
3. Size diminution in goats was largely complete by late Period I, in cattle by Period II, and in sheep perhaps not until Period III.
4. The development of animal keeping by the ancient inhabitants of Mehrgarh took place in the context of cereal crop cultivation, the building of substantial mud brick structures, and the existence of social differentiation and long distance trade networks as attested by the presence of marine shells, lapis lazuli, and turquoise in even the earliest graves (p. 311).

From this evidence one can see that the development of food production and the domestication of the plants and animals appears to have been a local phenomenon, not one that came to the subcontinent by diffusion from the west.

### Crops and Herds: Hunters, Gatherers, and Fishermen

From about 5000 B.C.E. the peoples of the Indus Valley and surrounding regions lived on a variety of food resources, both domesticated and wild. The base of the diet would have been the two cereals: barley first, and wheat second. They also cultivated various peas, beans and other pulses and exploited dates. Cotton seeds may have been present in Period II at Mehrgarh. One generally thinks of cotton as a fiber crop, but cotton oil is an important and nutritious commodity. Sesame was also domesticated in the Indus region, almost certainly for its oil. Most of these crops are grown in the winter season. For many millennia winter was the principal agricultural growing season in the subcontinent.

Extensive archaeology and archaeobotanical work in Gujarat, the southeastern “domain” of the Indus civilization, has produced evidence for the breadth of food resources used by the Indus peoples. A pot filled with seeds was recovered from the site of Surkotada. A number of seeds belonged to cultigens like Italian foxtail millet, green foxtail, and finger millet. The foxtail millet and finger millet were also found at the Sorath Harappan site of Rojdi (Weber, p. 119).

The chicken seems to have been first domesticated in China, but a case can be made that this was separately accomplished in the Indus region, where it is descended from the Indian Red Jungle Fowl, a beautifully colored bird. The male is a glossy deep orange-red, with long, yellowish neck feathers. The tail is shiny metallic black with long, arching sickle-shaped feathers. The underparts of the wild bird are blackish brown. This magnificent creature shares little in common with the almost pathetic white broiler stock now raised around the world. The wild chickens were eaten, and the eggs were probably a part of the diet.

Sedentary, village-based agriculture was complemented by herding, hunting and the gathering of additional plants. This served to expand and broaden the food base. We know from extensive analysis of animal remains that the peoples of the Indus civilization were cattle keepers on a grand scale. They also kept domesticated sheep and goats, as well as water buffalo. These animals were the source of a host of products from food to traction and of valuable materials such as fiber, leather, sinew, bone, and horn. Milk and milk products would have been very important to the Indus peoples. It is interesting to note that the subcontinent has never been a place where cheeses were prepared, but butter, *ghee* (clarified butter), and various forms of yogurt are widely known and may have their beginnings in the period being discussed here. The pig seems to have stayed wild, but it was hunted along with the animals listed above as “big game” that were not domesticated. Pigs and elephants were the source of ivory for the Indus peoples.

The aforementioned pot from Surkotada also produced large numbers of seeds from wild grass and sedges and other wild plants. This, and parallel evidence from Rojdi, informs us that gathering of wild plant material was an important part of the subsistence strategy, at least in some places. The Indian jujube was then, and is today, another food product gathered from wild trees.

Evidence for the use of fish and shellfish is spotty and not robust in the Indus region prior to the Indus civilization. After about 2500 B.C.E., however, the use of these maritime and riverine resources increased markedly. It is clear, for example, that fish contributed significantly to the diet of the Harappan inhabitants of Balakot, just to the west of Karachi near Sonmiani Bay on the coast of the Arabian Sea. They were eating a grunt, a fish that inhabits lagoons and sea areas with sandy bottoms and is taken today by fishermen who use gill nets in Sonmiani Bay. The peoples of the Indus civilization were great fish lovers. The Indus River teems with various species that were caught and eaten. The Harappans made very nice copper or bronze fishhooks, with an eye to take the line (Fig. 3).

Large fish vertebrae have been found at some Kutch Harappan sites. Salted and/or dried fish were traded over large distances during the Mature Harappan, as documented by the presence of a marine species at the Indus civilization city of Harappa.

The peoples of the Indus civilization ate considerable quantities of shellfish and turned the shells into beautiful artifacts: bangles, beads, ladles, figurines, rings, and inlay. The gastropods included five “shank” type shells and three bivalves, or clamlike animals. At Balakot one species of “shank” and the grunt seem to have dominated the diet of the Harappans.

We do know that these protohistoric peoples ate plenty of meat, including beef. Whether any of them were vegetarians has not been determined. Some of them could have been, but the widespread modern Indian tradition of vegetarianism, and the special respect that Hindus have for cattle, came later. Modern Indian vegetarianism has many bases, but key to it historically is the philosophical concept of *ahimsa* (noninjury), which is a part of the In-

FIGURE 3

dian intellectual achievement of the second half of the first millennium B.C.E.

Dietary Innovation with African Millets

The food grains of the early Indus Age were winter grasses, barley, and wheat. These do well in the north-western region of the subcontinent where there is enough winter rain and snow to sustain them. But the main period of rainfall for the subcontinent as a whole is the summer monsoon, which lasts from June to November. This is the hot season, and the winter grasses, as well as the other winter crops that the peoples of the Indus Age used, were not well adapted to it. It turns out that the subcontinent does not have any large-seeded summer-season cereals that could be domesticated, so there was something of an environmental bind for the expansion of agriculture outside the northwestern region with its winter rainfall.

This environmental bind was broken to a large extent when three millets from Africa became available to the farmers of ancient India. These plants were sorghum, pearl millet, and finger millet, all of which evolved in a belt across Africa just below the southern margin of the Sahara desert. Evidence for maritime trade between the Indus civilization and Mesopotamia comes to us from cuneiform texts and artifacts recovered from archaeological excavations. The texts speak of Mesopotamian venture capitalists who mounted maritime trading expeditions to three lands: Dilmun, Magan, and Meluhha, identified in order as Bahrain Island, Oman, and the Indus civilization (Possehl 1997: 133–137). They brought large quantities of copper back to Mesopotamia. Sailors of the Indus civilization reached Oman and the Arabian Gulf, since quantities of common Indus pottery have been found there along with other Indus artifacts.

The presence of the African millets in archaeological sites dating from 2400 to 2000 B.C.E. in Yemen, Oman, and the subcontinent implies that one leg of this maritime trade extended to the mouth of the Red Sea, where Indus sailors, probably short on food supplies, acquired local grains (the millets) for the trip home. These are the large-seeded summer cereals on which an entire subsistence system can be based. They begin to appear in the archaeological record of the Indus civilization about 2400 B.C.E.—first finger millet, then pearl millet, and finally sorghum at the end of the third millennium.

The resulting modification to the subcontinent’s subsistence pattern was slow and complex. The process was certainly not linear, with millets replacing other crops, and the massive acceptance of farming by hunter-gatherers. But over time these three African millets have made a massive contribution to the Indian economy because they were so well adapted to the summer monsoon wet season. Some measure of this success can be seen in modern statistics on cereal production in India. The three African millets are all in the list of the six most productive cereals, as seen in Table 1.

TABLE 1

Production of the top six cereals in India	
Grain	Amount in thousands of tons
Rice	70,667
Wheat	53,995
Sorghum	10,518
Corn	8,332
Pearl Millet	7,787
Finger Millet	2,379
All cereals	156,550

Ceramics and Food

Archaeologists have identified a few pottery shapes that can be associated with food and cooking in specific enough ways that they are interesting to talk about. There is a cooking pot, today called a *handi* in most north Indian languages (Fig. 4).

FIGURE 4

Shards from the bottoms of these pots are often fire-blackened, and they were sometimes protected against thermal shock with a coating of clay placed on the bottom after the pot was fired. The dish- or bowl-on-stand (Fig. 5). looks like a raised plate, just the sort of thing

FIGURE 5

that a person who ate sitting on the floor would use to raise his or her dinner closer to the mouth. There are lots of globular pots, often with surface treatments that significantly increase the surface area of the pot. One of these ceramic types is called “wet ware” (Fig. 6), which

FIGURE 6

was made by applying a viscous slurry of very fine clay over the body of a formed pot. The resulting pattern is both a decoration and functional since the many ridges increase the surface area of the pot, allowing for maximum evaporation, which kept the water in them cool. There are also small teacups (Fig. 7) with perforated han-

FIGURE 7

dles, which look much like their modern counterparts, and probably functioned in much the same way, as well as copper-bronze frying pans (Fig. 8).

FIGURE 8

## Food and Eating in Ancient India

Based on what is known one can imagine an eating scene in a home during the Indus civilization. People seem to have eaten while sitting on the floor, which was probably covered with a rug or a mat. They were served their food in a dish or bowl on a stand. The meal could have included flat, unleavened bread of barely or wheat flour, ground at home between stones. This would have been accompanied by meat: chicken, goat, sheep, water buffalo, or even beef. At times the flesh of wild ungulates would have been available. Fish and shellfish would have broadened this portion of the diet. Various peas and pulses would have added a vegetable component to the meals; and chicken eggs may have been included. A fruit component to the meal, possibly a dessert, would have come from honey, dates, grapes and the jujube. Milk from cows, buffalo, sheep and goats would have been available, and could have added great diversity of taste to the ancient diet. Cool liquids would have come from spherical pots, like those in wet ware, and been consumed in ceramic tableware, possibly even the little tea cups. Although butter was probably prepared, since it goes rancid so quickly in hot climates, the more stable clarified form, known as *ghee* in contemporary India, was also prepared. Other oils, for cooking and consumption, would have come from sesame and cotton seeds.

Cooking would have included roasting, boiling, and baking, as suggested by the *handi*-shaped pots, and frying, as documented by the copper-bronze frying pans. By 1500 B.C.E. the *tandoor*, a clay oven, is documented. This implies that this distinctive cuisine of modern India and Pakistan has a 3,500-year history.

There would have been almost no refrigeration, so many foods would have been eaten fresh, and seasonal availability would have had an important impact on the diet. But some forms of preservation were probably known. Food grains can be stored for years if kept dry. Clarified butter keeps for months. Dried and/or salted meat and fish are implied by the presence of maritime fish at Harappa, five hundred miles from the sea.

There is much to be learned on this topic of food in protohistoric times in South Asia. But there is an outline, and that will surely be filled out over time.

**INSPECTION.** Among the many systems that assure food safety, inspection is one of the most critical and difficult. As the global trade of food increased over time, veterinary experts of the Organization International des Epizooties (OIE) addressed the scientific challenge of confining animal diseases, which are the origin of most food-borne pathogens. In 1951 the spread of plant pests through trade became the concern of the International Plant Protection Committee (IPPC) of the Food and Agriculture Organization (FAO). As a result, the World Health Organization (WHO) and FAO organized a set of international standards, the Codex Alimentarius, which describes preferred methods of food production to minimize contaminants and toxicants to keep them below acceptable tolerance levels, with recommendations from the OIE and IPPC. In the early twenty-first century, the Sanitary and Phytosanitary Agreement (SPS) was the system that governed how inspection standards may be used in the fair trade of foods. This agreement was established by members of the 1994 Uruguay Round of the General Agreement on Tariffs and Trade (GATT). Together, Codex and SPS work to improve the quality of traded foods, limit the movement of crop pests and animal diseases, and mediate fair trade.

In the United States, inspection is performed by several different agencies, such as the Department of Agriculture, the Food and Drug Administration, the National Oceanographic and Aeronautic Administration, and the U.S. Customs Service. The following laws empower these agencies to perform inspections: the Federal Meat Inspection Act (1906), the Seafood Inspection Act (1934), and the Federal Food, Drug, and Cosmetic Act (1938) (Table 1). While the U.S. Department of Agriculture (USDA) cannot demand that a plant be closed, and while product recalls are voluntary, the withdrawal of all inspectors effectively means a plant can no longer ship its products since inspection is mandatory. The Food and Drug Administration (FDA) has authority to inspect food production facilities overseas, reject foods from entry into the United States, and even pull defective products off of store shelves.

U.S. Customs authorities assist in processing food imports at 150 ports of entry. In 2000, the FDA's limited resources allowed direct physical inspection of only 1 percent of imports. Still the system manages to catch problems (logging in over eight million lines of import

TABLE 1

U.S. food inspection system		
Food	Agency/office	Target
Meat, poultry, and processed egg products	USDA Food Safety and Inspection Service (FSIS)	Pathogens, filth, drug residues
Imported plants and pests, live animals	USDA Animal and Plant Health Inspection Service (APHIS)	Crop diseases
Fresh plant foods and eggs, processed foods, seafood, and dairy	FDA Office of Regulatory Affairs (ORA)	Pathogens, toxins, filth, pesticides, additives

detentions annually). In one season the reasons given for rejection of imports included: filth (32 percent); microbial pathogens and molds (17 percent); low-acid canned foods (12.5 percent); defective or misleading labeling (10 percent); pesticides and heavy metals (11.5 percent); decomposition (7.5 percent); and food additives (6.5 percent).

If an inspector suspects that products are unsafe, items can be detained automatically (especially if a number of previous shipments have been defective). An agency usually has a month to test the product and make a decision on its admissibility, but the importer may apply for early release after five days if the product is perishable. Permanently detained food must be remanufactured to acceptable standards, destroyed, or removed from the country within a certain period of time (three months in the United States).

In other countries inspection of imports may be a local, national, or regional endeavor. The Canadian Food Inspection Agency (CFIA) is the inspection authority in that country. In Central America, the Organismo Internacional Regional de Sanidad Agropecuaria, or International Regional Organization for Plant and Animal Sanitation (OIRSA), is the agency responsible for testing imports and assuring their safety.

Issues that arise from inspection are of two main types: political and scientific. First, if the reason for detention of an inspected food item is not transparent and scientifically valid, the importing country may be accused of erecting a trade barrier. Second, adequate sampling and testing are technically difficult. Traditionally, meat and poultry were inspected through organoleptic or sensory evaluation (smell, sight, touch), which worked for detection of gross filth, decomposition, and molds, but not for detection of microbial pathogens. Agents have begun to perform microbiological tests on meat and poultry, but such tests must be rapid, accurate, and relatively inexpensive to be useful. Perishable foods that are detained too long may not be fit for consumption by the time test results are available. Tests for many pathogens

are still in development; agents often test for common pathogens like salmonella and *E. coli*, which serve as biomarkers for the existence of other pathogens in a food sample.

Even when an excellent testing procedure is available, sampling poses a problem, especially in the case of solid or semi-solid foods. Contamination may be isolated in one part of a carcass, a head of lettuce, or a production run of some other food. Sampling the entire product would eliminate the worry that a pathogen was missed, but there would be no product left to eat. Thus an elaborate science of statistical testing has evolved to ascertain with reasonable probability whether a product is contaminated based on a certain number of samples of a certain size. Still, there is no guarantee that the product is safe or that subsequent abuse will not render it unsafe.

To streamline the inspection process, many countries require government-validated export certificates to verify whether a product contains what the label says it does and that it has been approved for safety and offered for consumption in the country that produces it. Making certification an internationally harmonious process is the focus of the Codex Committee for Food Import and Export Inspection and Certification Systems.

**INTAKE.** Intake is an umbrella term that refers to the act of taking something in. The term “intake” is often used in relation to food and drink, to describe how and how much is ingested. It also relates to behavior, since mental processing is involved in the action of eating and drinking. That is, physical and social stimuli are involved in feeding and drinking behaviors in terms of controlling the movements of gathering and ingesting materials; internal stimuli such as metabolism and circulating substrates also play a role. Intake of food and drink interests natural and social sciences as it is a vital behavior to sustain life that is also shaped by culture and society.

#### Behavioral Organization of Intake

The behavioral organization of intake involves perception of the sensory characteristics of food and drink. Physical and chemical properties of food and drink that can be sensed by the eater provide information about their nature. Orosensory attributes (that is, those relating to both taste and the other senses) can be detected by sight and sound, smell, irritation, taste, and touch. Food and drink can be appealing based on their orosensory properties. And the first mouthfuls of food can send substrates around the body within minutes.

Intake can be adjusted according to nutritional needs when orosensory characteristics are associated with the postingestive (metabolic) effects of food and drink. Orosensory characteristics can thus become cues that predict postingestional effects specific to foods and drinks. These cues can be unlearned (innate, sweet taste) or learned (acquired, bitter taste). While sweet stimuli mean energy, perhaps from carbohydrate, bitter stimuli are a cue to alkaloid toxins. From an evolutionary standpoint, it has been hypothesized that the liking for sweetness ensured animals' survival. In animals and humans, learning plays an important role in food intake. The acquisition of a taste for nutrients and an aversion for toxic substance are also vital. Behavioral and physiological analysis of the learning of pre- and postingestive control of intake was developed by French physiologist Jacques Le Magnen. His original contributions include findings on conditioned sensory aversions, carbohydrate-conditioned sensory preferences, and control of meal size.

#### Social and Cultural Organization of Intake

Intake is also organized according to food availability. In terms of the latter, we see the great contrast between industrialized countries where food is available in abundance and Third World countries where hunger afflicts poor people due to food scarcity. Our ancestors' intake was mainly dependent on plant food gathering, hunting, and fishing. Later on, domestication of food and animals and the development of food preservation enabled human societies to improve food availability. However, in parts of the world not well suited for cultivation, pastoralists still acquire their food from their herds of domesticated animals. Herding allows them to transform nonedible plant matter into animal products.

Intake is also determined by the culture of human groups. Learned cultural knowledge affects food choices. Socially transmitted knowledge about food includes norms, religious, or cult values, as well as myths, superstitions, taboos, and fads. The intake of certain kinds of plant and animal foods can be culturally prohibited. For example, cattle are killed for meat in many parts of the world, while traditional Hindus forbid killing cattle for meat because of their use in agriculture. Dogs serve as pets and companions in American culture while serving as food in other cultures, illustrating how intake is motivated by symbolic values of the food rather than its sur-

vival value. However, sociocultural influences do not act alone and interact with the individual's biology to determine intake.

### Control of Intake

Investigations concerned with the control of intake have used various peripheral and central approaches. This has led to theories of the mechanisms controlling intake, such as the glucostatic (transient change of blood glucose), the lipostatic (fat metabolism and body fat stores), the thermostatic (thermic effect of food), and the aminostatic (essential amino acid) hypotheses. Although intake was shown to be facilitated or inhibited by a variety of substrates, the behavioral mechanisms remain to be identified. Neural bases of food intake have evolved from the those prevalent in the 1950s, focusing on appetite and satiety brain centers located in the hypothalamus, to the current hypothesis that macronutrient intake is controlled by precise synaptic pathways. Food intake might indeed be guided by macronutrient selection. However, experiments that involve presenting laboratory animals with two or more diets differing in their nutrient content in an attempt to understand brain mechanisms that control intake involves the inclusion of confounding factors. Indeed, many drugs that affect central nervous system neurotransmitters and peptides also act on sensory pathways. Therefore, unless the confounding sensory attributes of food have been excluded, one cannot conclude that the subsequent food intake is controlled by the macronutrients. This principle was applied by examining studies using sensorily contrasting forms of various macronutrients, and only brain serotonin was found to affect carbohydrate intake while the effects of catecholamines and opiates on macronutrients were not substantiated.

Intake is also motivated by factors external to the food or the drink itself. Age, sex, physiological state, nutritional state, emotions, stress, number of people present, peer groups, food trends, social pressures (body image), as well as beliefs related to food safety (for example, food beliefs related to mad cow disease, genetically modified foods, pesticide-free or organic food) are known to influence intake. Other external factors that affect intake include food availability, food cost, as well as environmental factors (season, temperature, and so forth). In addition, animal and human studies have revealed that food and macronutrient intake is related to circadian rhythms, and that food intake is concentrated during the period of main activity (for example, during the day) and is related to predictable rhythms of macronutrient selection.

### Expressing Intake

Intake of food and drink is often estimated by dietary measurement of daily intake of energy (kilocalorie [kcal], kilojoules [kJ]) and nutrients (carbohydrate, protein, lipid, vitamins, and minerals. Units such as the gram (g),

milligram (mg), microgram ( $\mu\text{g}$ ), International Unit (IU), and so forth are used, as well as established human nutrition methodologies such as food diary, food recalls, food frequency questionnaires, and so on. Intakes are then qualified as adequate or inadequate based on nutritional recommendations. Nutritional research methods need to be improved by assessing cognitive perception and control of eating.

Facilitated intake and its inhibition are expressed in various ways. Among terms used to describe facilitated intake or events surrounding it are appetite, hunger, palatability, motivation to eat, and (sensory) preference. If intake is inhibited, terms such as satiety, satiation, appetite inhibition, or even satiety disinhibition are used. These terms are often used to interpret sets of quantitative data such as amount eaten during the day, meal size, ingestion rate, or numbers calculated from scales rating the hunger state. Although these measurements do not assess cognitive processes controlling intake, their direction is translated into words describing behaviors. The experimental design is therefore crucial to identify causal processes involved in intake; for example, unchanged quantitative intake while rate of intake is reduced could be interpreted as decreased pleasure while sensory preference remains unaffected.

### Implications

Insufficient intake results in chronic malnutrition and periodic massive starvation. Related health problems are numerous, and include the impact of the permanent effect of energy-protein deficiency on brain development (in early childhood), parasitic diseases, and high rates of infant mortality. Controlling population growth and a better allocation of resources were proposed as solutions to world hunger. The problem of hunger could also be alleviated by technology transfer in which new technologies and crop variety could improve food production.

Disordered intake can lead to health problems such as obesity, cardiovascular disease, diabetes, alcoholism, as well as disordered eating in athletes and the eating disorders of restrictive eaters, anorexics, and bulimics. Interestingly, these health problems often arise in countries where food is abundant. Intake of specific macronutrients has been linked to diseases, for example, intake of carbohydrates has been linked to diabetes, and fat intake has been linked to heart disease, as well as to some cancers. Therefore, a better understanding of how intake is controlled could provide precious tools enabling one to intervene effectively or even prevent the development of nutrition-related pathologies.

**INTERNATIONAL AGENCIES.** The second half of the twentieth century witnessed the growth of a type of social institution that plays an important role in food and nutrition policies and programs throughout the world. These institutions, which are commonly referred to as "international agencies," are usually constituted as suborganizations within larger sociopolitical organizational structures. One set of such institutions are the "multilaterals," which include many governments, particularly the agencies of the United Nations (UN), or those of the European Union. A second set of agencies, often referred to as "bilaterals," are the aid organizations established by national governments in the industrialized world, including those of the European states, the United States, and Canada, as well as Australia and Japan. A third type, with activities that closely parallel those of the UN and governmental agencies, includes nongovernmental organizations (NGOs) or private voluntary organizations (PVOs). These may be religious or "faith-based" agencies that are administratively connected to religious organizations or are closely affiliated with such organizations, or they may be independent groups, such as the Helen Keller Foundation or Save the Children. Many of these NGOs receive funds from bilateral and multilateral agencies.

### Agencies of the United Nations

The establishment of the various agencies in the UN system began with the founding of the UN in 1945. During the following half-century, new agencies were added as needs were redefined and expanded. The current body of UN agencies whose work involves food and/or nutrition are the Asian Development Bank (ADB), Food and Agriculture Organization (FAO), International Atomic Energy Agency (IAEA), International Fund for Agricul-

tural Development (IFAD), International Labor Organization (ILO), Joint United Nations Programme on HIV/AIDS (UNAIDS), United Nations Development Programme (UNDP), United Nations Educational, Scientific, and Cultural Organization (UNESCO), United Nations Population Fund (UNFPA), United Nations High Commissioner for Refugees (UNHCR), United Nations Children's Fund (UNICEF), United Nations Research Institute for Social Development (UNRISD), World Food Programme (WFP), World Health Organization (WHO), and the World Bank.

### Agency Goals and Functions

One of the principal motivations underlying the establishment and operation of international agencies was to provide vehicles for directing resources—economic, technical, and technological—from resource-rich countries to resource-poor countries. Other political, economic, and social interests also shape the motivations and activities of agencies. Moreover, the fact that international agencies are generally not freestanding institutions, but part of larger sociopolitical units, is one of several characteristics that affect their mission, administrative organization, philosophy, policy, and activities.

The purposes of both UN and non-UN agencies whose work relates to food and nutrition can be summarized by one or more of the following goals: establishing technical norms, providing funding, providing technical assistance, or delivering services. Within the UN system, the various agencies were established with distinct, yet complementary, mandates and were given different, but often overlapping, sectors of action. Thus, WHO and FAO were set up as technical agencies with responsibilities for technical norms and technical assistance, whereas UNICEF was designed to support and deliver services through funding and technical support, and the World Bank was designed to provide funds.

### Obstacles, Challenges, and Persistence

In their efforts to further the health and welfare of populations with respect to food and nutrition, international agencies face multiple challenges. An examination of these challenges helps to explain the gaps between stated goals and realities of agency activities that make them frequent subjects of controversy and criticism. Some of these challenges relate to the structure of international collaboration and conflict regardless of the focus of action, while others are specific to characteristics of social action related to food and nutrition.

A primary challenge for establishing complementary activities at country and community levels is that agencies' activities are based on widely differing philosophies of how to promote and sustain development. Bilateral agencies represent countries with different economic and political agendas. These differ not only between nations, but also within nations, as is evident from the policy changes that accompany shifts in government when dif-

ferent political parties are in power. Within the UN system itself, there are also different philosophies and constituencies, which are evident not only between agencies, but also within them. The NGOs and PVOs represent still other sets of values and theories about what needs to be done and how to do it.

International agencies face serious challenges in reconciling definitions of needs as perceived on one hand by technical advisers, high-level political representatives, and international advocacy groups, and on the other with the needs articulated by recipient groups, from national-level politicians and civil administrators to regional and community-level spokesmen. These conflicting interpretations arise from multiple sources and cover a range of issues, including ethical concerns and competing values about fairness, justice and “whose reality counts,” priorities for action in the face of limited resources, and differing perspectives on the causes and consequences of food and nutrition problems. A related factor that affects many aspects of food and nutrition policies and programs is that most agencies, especially the bilaterals, have to answer to the political constituencies who control the resources they require to carry out their work. Indeed the basic organization of development activities into the categories of “donors” and “recipients” create structural barriers that pose significant challenges to meeting population needs.

Another common problem, which relates to the demands from “donor constituencies,” is that the time frame for research, program development, and evaluation is typically much too short. As a consequence, agencies are forced to take shortcuts that jeopardize the achievement of goals. As a result, the potential to learn from experience is reduced, and there are inadequate opportunities to make adjustments to improve programs.

Special challenges for food and nutrition activities stem from the fact that throughout the world they relate to multiple and very different social sectors. Food is the provenance of agriculture and various economic sectors of producers and marketing concerns. It is also the source of nutrients, which are the provenance of nutrition and health sectors. Both national governments and international agencies tend to divide food and nutrition responsibilities among multiple organizational units, which often results in conflicting goals and serious fragmentation of efforts. Even within a particular sector, such as health agencies, differing orientations may result in conflicting approaches to nutrition and health education in communities.

In 1977 the UN established the Subcommittee on Nutrition (SCN), under the aegis of the Administrative Committee on Coordination (ACC), as a mechanism for communication among the various UN agencies with responsibilities in food and nutrition. The ACC/SCN, which meets yearly and compiles and disseminates technical reports through its office in Geneva, Switzerland, also seeks the participation of bilaterals and NGOs. This

small organization has no mandated authority to resolve differences but provides a forum for exchange and debate. Its existence is threatened by hostility from some of its constituent agencies who fear that SCN activities may reveal weaknesses in their own operations, and at least one of SCN's components, the Advisory Group on Nutrition (AGN), which was composed of senior experts from outside the UN system, has been dismantled.

The example of the tribulations of the SCN provides a glimpse of the shortcomings in motivations, organization, and action that are typical of international agencies. There are, however, two critical questions to answer before recommending curtailing or abolishing these agencies. The first is, “Would the poor and hungry be better off without these agencies?” Historical comparisons of situations where the agencies have and have not been active reveal that the presence of the agencies has been favorable. Without them, the only major interests affecting food and nutrition are commercial and political—neither of which care much about the poor.

The second question is, "Can the system or its constituents be improved?" Greater intellectual attention is required to address such important issues as updating the mandates of international agencies to modern realities, instituting better accountability for all international agencies (including bilaterals and NGOs), and increasing resources to improve diet and nutrition worldwide. At the level of agencies, a high priority is developing better methods for more effective cooperation between agencies and populations. While there are many difficult barriers to improving agency functioning, dedicated people who work in and with international agencies find many opportunities to make improvements.

**INTESTINAL FLORA.** "The entire world is covered with a layer of feces. Granted it is thicker in some places than in others, but a solid layer, nevertheless. . . ." This is how a wizened professor used to begin his clinical parasitology course for microbiology graduate students. Naturally all the students laughed, only to learn during the ensuing months that the statement is profoundly true. The lesson also bears truth in that fecal microorganisms arise from within the bowels of the digestive tract. The human intestine is home to an invisible and remarkable biosphere of living organisms dedicated to preserving its own existence. Humans serve as host to these billions and trillions of organisms that function in effect as a single living entity.

In fair exchange, during our lifespan, our gut flora provides us with health, protects us from disease, and serves as the major labor force to digest almost everything we eat—from artichokes to zebu.

The population of microbes that inhabit our intestines is made up of hundreds of different species of bacteria and other organisms. By far the vast majority of these are anaerobic, which means they do not multiply in the presence of oxygen. Since few if any anaerobes are defined as classic pathogens, by and large these anaerobes are only of interest to culinarians because they function to metabolize and break down what we eat and make it available to be absorbed and used as fuel and energy for our own body. Other species that require air (oxygen) to live are more commonly known by the general public, and a few have even achieved stardom, mainly because of their predilection to cause disease. Thus, certain bacteria such as *staphylococcus*, *E. coli*, *salmonella*, *shigella*, *enterobacter*, and others have become well recognized, if not feared—almost to the point of being a phobia—by some people, especially in the United States. Most peo-

ple seem to be confused by too many overstated, highly publicized warnings, along with too many recommendations from too many different sources.

A list of the scientific names of all the different microorganisms that inhabit the human gut, sometimes described as autochthonous flora, would be very lengthy. Some understanding of science is required, however, in order to appreciate the very complex relationship we have with the microbial world living inside and on our bodies, which in turn help maintain the delicate balance between health and disease. Most important is the fact that each living human being has a rather steadfast and distinct microbial profile. This profile is almost as identifiable as a fingerprint.

When foreign bacteria are introduced to our profile, the ecosystem reacts rather quickly to disallow these species to proliferate. Accordingly, disease is not a normal finding; rather, we, for most of our existence, maintain ourselves in a general state of good health.

Some remarkable studies have demonstrated that even when our intestinal microbiologic profile is disrupted to the point of causing disease, for instance, in the case of traveler's diarrhea, the body mounts a tremendous effort to return itself to its normal healthful state, and in doing so somehow the original microbial profile returns. What we eat and how old we are does play a major role in the overall state of our live-in microbial population, and on occasion shifts of our profile do occur. For example, this happens when the microbes adjust to accommodate the various types of food we ingest. So, if we eat a diet of all starches, those species of organisms which thrive on starches will increase their relative numbers in relation to the frequency and amount of starch which we consume. When one considers diseases that are due to intestinal microbiota, it is also important to know what "pathologic bolus" means. Simply put, this phrase refers to the minimal number of pathogenic organisms needed to be ingested in order to cause a specific disease. It is usually expressed as numbers in powers of ten per gram or milliliter of menstroom. This number ranges from very large to very small, depending on the specific organism and disease. So, while certain diseases require huge numbers of bacteria in order to initiate illness, others require very few bacteria.

For example, not all *salmonella* species are pathogenic, and those that are generally require that a large pathologic bolus be ingested to produce illness. On the other hand, most species of *shigella* are intrinsically "pathogenic," and it takes only a small number to cause symptoms. It has been found, in this example, that *salmonellae* generally are susceptible to destruction by acidity of the stomach, and few survive to enter the intestines where the actual infection takes place. Shigellae, on the other hand, are able to withstand the acidity of our gastric juices and arrive in the intestine viable and ready to set up (unwanted) residence and cause disease.

Other major factors also play heavily in defining health and disease. Paramount to this struggle are the status of our overall nutritional habits and secondly the maintenance of the immune system and understanding how it functions to protect us from invading organisms.

In general, well-fed people are less likely to catch infectious diseases of any sort, and with some exceptions, the incidence and severity of dysenterylike diseases are also lessened if we follow a well-balanced diet. The amazing increase in the average height of individuals after the introduction of better food and balanced diets in certain Third World populations, which occurred in one single generation, is testimony to the tremendous impact diet plays in this regard. Individuals who suffer from underlying diseases and conditions that compromise the normal function of our immune system are much more vulnerable to life-threatening diseases caused by bacteria, viruses, and other organisms than are average citizens. Likewise, those who have lost protection due to impairment or destruction of the skin are much more likely to become ill. The causative agents in these cases are produced not only by recognized pathogens, but also come from normally benign species of so-called normal (or commensal) flora. Almost 90 percent of mortalities in burn patients are due to infection and sepsis. Furthermore, most of these deadly infections are produced by the patient's own intrinsic internal microorganisms. Notable for this discussion is that most foodborne diseases are indeed usually attributed to microbial species of the enteric type—"enteric" meaning those normally found in the digestive tract. When they are allowed to proliferate in nutrient-rich unrefrigerated foods such as potato salad, bacterial and viral "food poisoning" is likely, and outbreaks continue to afflict even the most civilized nations.

The most common cause of both direct and cross-contamination of foods, which ultimately can lead to such outbreaks, is unofficially labeled in medical vernacular the "fecal/hand/mouth" route—not a polite description, but accurate. Furthermore, although refrigeration and proper storage—and to a lesser degree chemical disinfection—are important, human hands remain the most villainous of vectors of food-borne disease. More important, frequent handwashing with regular soap and hot water remains the absolute best means of prevention.

**INTRAVENOUS FEEDING.** See **Enteral and Parenteral Nutrition.**

**INUIT.** The northern indigenous peoples known as Eskimo or Inuit (not including the Russian Inuit and Yupiget) numbered approximately 143,582 in 2002. In the United States, Alaskan Eskimos (Inuit, Yupiit, Yupiget, and others) numbered 55,674 according to the 1990 census (U.S. Bureau of the Census, personal communication, May 2002). In Canada, Inuit numbered 41,800 in the 1996 census, while the nation of Greenland, formerly a Danish territory, had an Inuit population of 46,108 in 2001. Alaskan Eskimos live in rural coastal villages, along northern rivers, in isolated island or northern interior valleys and, increasingly, in regional population centers such as Anchorage, Barrow, Fairbanks, Kotzebue, and Nome. In Canada, despite rising migration rates to the south, most Inuit live in fifty-five rural communities located in Nunavut, the Northwest Territories, Quebec province, Newfoundland, and Labrador. In Greenland, too, Inuit live in coastal villages, although those who live in population centers such as Nuuk are increasing.

In Alaska, Canada, and Greenland, names such as Inuit, Yupiit, and Yupiget identify Eskimos as "the people" or "the real people." Regardless of location or name, food is a critical feature of identity for all. (The term "Eskimo" is used here because it includes all groups.) Identity is often expressed as a longing for locally harvested and prepared foods by those who find themselves separated from traditional homeland communities. Local foods are referred to as "our" food, "real" food, or, in Alaska, simply "Eskimo" food. In Canada, such foods are called "country" food. Among the Alaskan Yupiget of St. Lawrence Island, for instance, the term *neqepik* means "real" food, while imported foods are called *laluramka* or "white people's" food (Jolles, 2002).

Across the north, dietary habits and cultural meanings attached to food are similar, due partly to adaptation to a common arctic ecosystem and partly to similar socioeconomic conditions, which keep unemployment rates as high as 50 to 80 percent. Under such conditions, subsistence-oriented hunting, fishing, and gathering activities, vital to community survival, are performed year-round. In Nunavut, Canada, alone, replacing subsistence foods with equivalent amounts of beef, chicken, and pork would cost an estimated \$30 to \$35 million annually.

Types of harvested foods depend on local environments and overall resource availability. In 2002, in In-

Whale and walrus meat drying in the open air at Hoopers Bay, Alaska. FROM AN ANTIQUE PHOTOGRAPH, COURTESY OF THE LIBRARY OF CONGRESS.

galiq, Little Diomed Island, Alaska, for example, severe weather plus political and physical isolation at the Russian-American border one mile distant necessitated a substantial dependence on local foods. Diomed subsistence resources include bearded seals, ringed seals, spotted seals, walrus, and polar bears. In summer, the community harvests migrating water fowl such as auklets, puffins, and murre, along with their eggs. In late summer, wild greens and berries are harvested and stored. In winter (December through mid-May), the community takes Alaska blue king crabs through the sea ice and trades a portion of the harvest with mainland Alaskan Eskimo communities for unavailable foods such as caribou. Altogether, Ingaliq subsistence foods include more than forty marine mammal, plant, avian, fish, and shellfish resources. Local harvests in Diomed and elsewhere in the North are supplemented with expensive, imported, commercially available goods from Native cooperative stores, Hudson Bay Company franchises, and other small multipurpose stores found throughout the north.

In Alaska, meat and fish are the centerpieces of Eskimo diets and constitute 90 percent of locally harvested foods. In addition, communities take several types of whales: bowhead, gray, minke, and beluga, or white. Reindeer (introduced in the late 1890s by the U.S. government and managed by local villages), moose, caribou, and a newly reintroduced resource, musk oxen (available to hunters in 1995) are also taken. Numerous migratory seabirds are hunted during late spring and early fall, as is the ptarmigan, a permanent resident. Fish are prominent in southwestern coastal diets, especially salmon. Herring, tomcod, Arctic char, grayling, flounder, sculpin, and halibut also contribute to the diet. Clams are taken from walrus stomachs. Ground squirrels, once commonly harvested for their furs and their meat, are seldom taken any more. While meat is the mainstay, wild greens and berries are much sought. At least thirty species of plants are collected for food purposes from the land and from the beaches (Jones, 1983; Schofield, 1989, 1993).

For Canadian Inuit, diet in the early twenty-first century also consisted of two major classes of food, Inuit food or “country” food, and *Qallunaat*, or “white people’s” food. “Country” foods include caribou, Arctic hare, ptarmigan, ringed seal, bearded seal, walrus, polar bear, beluga whale, migrating fish (Arctic char, Atlantic salmon, and Pacific salmon), and migratory birds (Canada goose, common eider, king eider, and black guillemots). “White people’s” food includes items shipped from southern Canada and purchased at local stores, including fresh fruits and vegetables, canned goods, processed foods, and dry goods.

In Alaska, especially in the most northern communities, it was once common to consume uncooked meats. This has become less common with the introduction of such modern conveniences as microwaves, refrigerators, propane-fueled stoves, and the like. However, in Canada, the preference for uncooked meats is still a significant cultural feature. This practice became a powerful marker of Inuit identity in the post-World War II era as Canadian Inuit experienced more sustained contact with Europeans and Canadians of European descent such as missionaries, teachers, and administrators. Consumption of raw or frozen foods, a practice typically disdained by non-Inuit, intensified boundaries separating Inuit and non-Inuit (Brody, 1975), and fostered increased social unity and political activism among Inuit who sought to protect and promote their hunting and fishing rights and to achieve local resource management in Inuit homelands.

Greenland Inuit obtain their food from two major sources: local land, seas, and lakes (called “country” food) and through local store purchases and via mail order. The main subsistence foods are ringed seal, beluga whale, caribou, bearded seal, and polar bear as well as a wide variety of fish, including cod, capelin, Atlantic salmon, Arctic char, and Greenland halibut. One feature that distinguishes the Inuit of Greenland from Canadian and Alaskan Eskimos is the abundance of small-scale fisheries, which include fish plants that provide a number of settlements with seasonal employment (Dahl, 2000). In addition to subsistence production, many Greenlandic Inuit are also involved in large-scale commercial fishing operations, and fishing products, including shrimp, Greenlandic halibut and crabs are Greenland’s major exports. Many of the companies are owned and maintained by Inuit. Finally, there are approximately sixty sheep farms in southwest Greenland that produce lamb and other products for both domestic and international markets.

Food management in Eskimo communities combines traditional practices with modern convenience. Subsistence meats are often “half-dried” on outdoor meat racks, cooked (boiled), and stored in containers of seal oil or, alternatively, stored in home freezers, either “half-dried” or fresh. Greens, roots, and berries are more often stored in freezers, although some residents also use seal oil. Traditional underground or semiunderground food caches are gradually becoming a part of the past,

while home freezer storage and consumption of fresh frozen foods has become increasingly common. In the late twentieth century and early twenty-first, in spite of significant changes in food storage methods, locally harvested foods from the land and the sea remained a major component of Eskimo food consumption. However, while “country” food or “real” food still defines ethnic and cultural boundaries in the North, “white people’s” food is increasingly popular among young people, whether in Alaska (Jolles, 2002), Canada, or Greenland (Searles, 2002). The presence of contaminants in locally harvested foods is a major concern in the Arctic, for example, PCP, and is under discussion in all of the affected regions. It is unclear how this information, along with changing lifeways, will modify Eskimo diets.

**IODINE.** Iodine is an essential dietary element necessary for normal development and function of all vertebrates. Its sole physiological function is as a constituent of the thyroid hormones, thyroxine and triiodothyronine. It is removed from the blood by the thyroid gland for storage in organic form where it is found as iodinated amino acids in peptide linkage in thyroglobulin, a high-molecular weight protein.

Iodine is widely but usually sparsely distributed in nature, so that in vast areas of the world the supply in customary diets is marginal or insufficient. It has been estimated that over two billion persons are at risk of disorders attributable to iodine deficiency. Among these disorders are goiter, impaired intellectual function, growth retardation, reduced fecundity, lowered work capacity, increased rates of fetal loss and infant mortality, deafness, and in extreme instances a well-defined but somewhat

varied constellation of physical findings collectively known as cretinism. Cretins are recognized by severe mental deficiency, disturbances in gait, impaired or absent hearing, and other neurological defects, but the signs and symptoms in these individuals may be subtle. These features merge with those of the less impaired members of the same community or nearby countryside where they may appear in lesser severity.

The iodine content of edible plants is largely dependent on the iodine content of the soil on which they are grown. The iodine content of foods of animal origin depends on the iodine in their food. Iodine is concentrated in milk, and is found in relatively high concentration in sea fish, who are at the upper levels of the food chain that contains algae. Some sea fish concentrate iodine from sea water. The only structure among the vertebrates that contains a significant amount of iodine is the thyroid gland.

#### Role of Iodine in Disease

For centuries the disorders arising from iodine deficiency have been recognized in well-defined regions. These have been called “goiter belts.” Switzerland was included in the goiter belt until the iodine deficiency in that country was corrected in the first half of the twentieth century. Until recent years iodine deficiency was a recognized disorder in the United States, especially the Midwest and West, where goiter was commonplace. Iodine deficiency has been a major public health problem in the Andean region and eastward, in large areas of central and north Africa, in the Middle Eastern countries, in India, and in eastern and central Europe, and even today in localized regions of western Europe. Fortunately, remarkable headway has been made in elimination of iodine deficiency through various methods of supplementing diets.

Goiter is only one of the many consequences of iodine deficiency, and is relatively trivial when compared with the damaging effects of iodine deficiency on the nervous system. From the human point of view, it is more correct to speak of “endemic mental deficiency” than “endemic goiter.”

Endemic thyroid disease has traditionally been considered a feature of iodine deficiency in the mountainous regions of the world. Endemic thyroid disease is found in regions of high elevation, but has also been common where glacial run-offs occur and in floodplains where there has been chronic leaching of the soil. Such geographic regions include the Gangetic plain and much of India and southeastern Asia, the Himalayan region, and central Africa, where the iodine deficiency disorders are frequent and severe; the coastal regions of western Europe are marginally iodine deficient. Endemic iodine deficiency can be detected almost anywhere with currently available sensitive techniques. In the United States until recently the mean intake of iodine was excessive, but recently has been rapidly falling into a normal range. The

recent precipitous fall in iodine consumption in the United States has led to concern that iodine deficiency may again become a problem if the present rate of decline continues. The need for monitoring iodine intake is apparent. This is customarily done by measuring the iodine content of urine from a fair sample of the population under observation.

The optimal daily adult iodine intake is about 150  $\mu$ g/day, about half that for children and infants. This figure rises to about 200  $\mu$ g during pregnancy, but under normal circumstances there is wide latitude in intake because of the ability of the normal thyroid system to compensate for varying levels of supply. The thyroid and pituitary through a feedback relationship provide a highly efficient regulatory system. If iodine intake falls below about 50  $\mu$ g/day the pituitary gland becomes stimulated to increase its iodine uptake and hormone production, and, if the iodine supply exceeds needs, the pituitary shuts down appropriately.

Iodine is readily absorbed by the stomach and upper gastrointestinal tract. Iodine in chemical combination is released in the gut and absorbed; it may be rapidly taken up by the thyroid gland or excreted in the urine. Only a small fraction appears in the stool. Exceptions occur when iodine is in chemical combination with such drugs used as radio-contrast agents and amiodarone, the widely used cardiac medication.

### **Iodine Deficiency and Disease**

Certain chemical agents found in some foods interfere with the uptake or utilization of iodine by the thyroid. Among these are the cyanoglycosides found in cassava (manioc), a component of millet, and a variety of chemical agents and some unidentified substances found in the effluent water from rock formations and in factory discharges. It must be stressed that the inhibitory effect of these substances may be bypassed if there is an ample supply of iodine in the diet, but their effect may be critical if the iodine intake is marginal or lower.

When marginal or low iodine intake is identified in a geographic regions such as a district or country, an effort should be made to correct the deficiency. A variety of techniques have been employed. These include distribution of iodine solution to school attendees, candies containing potassium iodide, addition of iodine to drinking water, and the use of canisters containing iodine that is slowly released into sources of drinking water. None of these methods has proved to be widely accepted. In addition, it should be stressed that the primary target for the prevention of neurological damage due to iodine deficiency is the pregnant and nursing mother.

### **Prevention of Iodine Deficiency**

The most effective and widely employed method for correcting iodine deficiency is salt iodization. The technique is simple, inexpensive, and effective. Potassium iodate rather than iodide salts is used because it is more stable

when mixed with salt. Nevertheless certain problems must be corrected. Unscrupulous traders may sharply increase the cost of iodized salt to the consumer. If improperly stored the iodine may sublime and be lost from the salt. If addition of iodine by the manufacturer is not done carefully the salt may be overiodinated. In certain cases, especially those in which people have nodular goiters resulting from prolonged iodine deficiency, thyrotoxicosis may result, which may be subtle in onset and chronic, with unwanted or disastrous results. Careful and continued monitoring of dietary supplementation by iodized salt must be done, as with all food additives.

Promotion of salt iodization, especially in areas of particular need in the developing world, has been a health priority of many public and private agencies, including the World Health Organization, UNICEF, the International Council for Prevention of the Iodine Deficiency Disorders, and others. One of the principal problems with programs of salt iodization is that governments tend to lose interest, and the programs lapse, leading to recurrence of the iodine deficiency disorders. Again, constant monitoring is the key to continued success.

Injections of heavily iodinated poppyseed and other oils have been tried in mass campaigns, first in New Guinea; these methods have since been widely employed elsewhere. These are the same oils that have been widely used as radio-contrast agents. The results have been impressive. The iodine is slowly released from the oil and may be effective for two or more years. The oral route has also been used to administer the oils, but effectiveness is less prolonged. The disadvantages of programs using iodinated oil are principally cost and the requirement for sterile needles and trained personnel, which may be difficult to obtain in remote regions. Iodine-induced thyrotoxicosis may occur after administration of iodinated oil.

A unique and successful method of iodine distribution has recently been introduced. This method can be used in regions where iodine can be drip-added to irrigation water. It has been used in the desert regions of western China with salutary human benefit, and with a highly satisfactory effect on livestock production. The problems with this method are the need for skilled personnel to add the iodine to the irrigation system at the right time and rate, and the fact that it is only feasible when it is possible to add iodine to irrigation water. A somewhat similar technique that has proved beneficial is adding iodine to a municipal water supply. As with other methods of iodine supplementation, skilled maintenance of the program is essential, and the subsequent appearance of thyrotoxicosis is unknown.

### **Summary**

Iodine is thinly distributed in the earth's crust, and much of the human population lives in regions that have marginal or insufficient iodine. Mountainous regions, floodplains, and regions where there has been extensive leaching of iodine from the soil may not provide suffi-

cient iodine for human needs. The result is the appearance of iodine deficiency disorders, which include neurological damage, goiter, increased fetal and infant mortality, deafness, and diminished human energy and resulting economic underproductivity. Iodine deficiency is a major public health problem for a large fraction of the world's population.

Wherever marginal or insufficient iodine exists, implementation of iodine supplementation is required. This may be done by supplementing table salt with iodine, administration of iodinated oil by injection or orally, or addition of iodine to the drinking water. It is essential that a monitoring system be in place to ensure that the population is receiving an adequate iodine intake. Care must be exercised to avoid an excess of iodine, which might induce thyrotoxicosis.

**IRAN.** The art of sophisticated cookery in Iran can be traced to antiquity. It has, according to existing literature, preserved its basic mode of preparation for more than a thousand years, enhanced by refinement of dishes and new recipes created in the kitchens of royalty and or-

Detail of a seventeenth-century miniature showing an outdoor banquet of Abbas I of Persia. The carafes on the small carpet contain red wine. © ARCHIVO ICONOGRAFICO, S.A./CORBIS.

dinary folk. Iranian food is prepared with such delicate subtlety that every ingredient used can be tasted and every aromatic spice added can be appreciated.

#### Food of Ancient Persia

**History.** The Persian Achaemenid empire, founded by Cyrus the Great in 549 B.C.E., dominated the ancient world for almost two centuries. At the height of its power it extended from the Indus in the east to Asia Minor and Egypt in the west, uniting Medes, Persians, and Parthians, as well as many other tribes and peoples, in fealty to the dynasty. Presumably the people living in that vast expanse with its varied climates each formed their own culinary culture according to indigenous food products, naturally available, grown, or reared. Yet all cultures converged at the Achaemenid court and were elaborately manifested at the table of the king of kings.

There are no known recipes left of that period. The references to food in the Avesta and Elamite tablets from Persepolis dated 509–494 B.C.E. indicate that the Achaemenid diet consisted of dairy products from cows, sheep, goats, and mares; meat from oxen, rams, goats, and wild or reared fowls; grains for making bread; ales; wines; dried fruit; and nuts and seeds also used for pressing oil.

Each season, the nomad kings and the court moved from capital to capital. Winter was spent in Babylon or Susa, where the wine was fermented from dates and grapes; spring in Ecbatana, where meat, dairy products, and herbs were ample; and autumn in Persepolis, where fruit, wild vegetables, and seeds were in abundance.

Narratives by Greek authors of the period reveal the sumptuous preparation and the abundance of food in that fertile realm. Ctesias (405–397 B.C.E.) and Dinon indicate that 15,000 men ate daily in the court of the Achaemenid king of kings. The Greek writer Polyaeus (second century C.E.) recounts that the food brought to the court for distribution as well as for the preparation of three meals a day was formulated by Cyrus and engraved on a bronze column. It included great quantities of different grades of wheat, barley, and rye, floured or treated; grains of corn and parsley; salt; male livestock; gazelles; poultry; geese; pigeons; small wild birds; dairy; watercress; onions and garlic; pickled radishes and beet-roots; cured capers; juice of sweet apples; conserve of sour pomegranates; honey; oils of almond, terebinth, sesame seed, and acanthus; raisins dark and light; nuts; sweetened seeds; vinegar; mustard, anise, cumin, celery, and safflower seeds; saffron; cardamom; and dill flower. Xenophon (430–355 B.C.E.) notes that what was served at the king's table was prepared in exquisite taste by expert cooks and bakers who were engaged in a constant search for new recipes and would invent a variety of pastries and cakes.

Herodotus (fifth century B.C.E.) relates that the Persians ate varied desserts and sweets. Birthdays were celebrated by giving great feasts. Side dishes, served at

regular intervals, punctuated the introduction of the principal dishes. Large animals, including big fowl like ostrich, were stuffed and roasted whole; birds were stuffed and seasoned with capers. Meat cured in sophisticated fashion was served.

The Greek historian Diodorus Siculus (first century B.C.E.) reflects on the variety of delicacies brought from Persia to Babylon, in particular fish from the Persian Gulf. Polyaeus remarks on the exquisite mixture of cardamom and other spices, vinegar, and pepper, and upon the use of aromatic herbs from which oil was also extracted for medicinal purposes.

It is said that soldiers normally received meat and bread, but on long journeys and campaigns were sustained by onion soup and bread. To this day *eshkaneh*, basically made with onions, flour, and turmeric, is cooked in different parts of Iran. Seasonal or dried herbs and fruit—dried or fresh—are added, and, combined with one or two eggs, the dish can serve a big family. It remains the food of the populace, while the stuffed beast or fowl, *boghblameh*, is served mainly at tribal feasts by those who can afford the luxury. Pierre Briant, quoting Polyaeus, remarks in *Histoire de l'Empire Perse* (p. 300) that when Alexander the Great defeated Darius III and seized Persepolis (331 B.C.E.), ordering the bronze pillars to be destroyed, he said with laughter that such a diet weakens the body and the mind and was the cause of the defeat of the Persians.

Following Alexander's demise, his successors, the Seleucid Greek rulers (323–64 B.C.E.), were overthrown by the Parthians of western Iran. The Parthians (250 B.C.E.–224 C.E.) revived the national spirit that came to

full flowering under their successors, the Sassanians (224–652 C.E.). The culinary culture of the aristocracy and preparation of food in this period are revealed in a rare Pahlavi manuscript, “King Husrav and His Boy” (translated: J. Unvala, Paris), a reliable source that withstood the destruction of libraries by the Islamic army in 636 or 637. In the text Khosrow II and a companion discuss, among the pleasures of life, the variety of Epicurean cuisine. Some dishes are in certain ways similar to what is eaten in the early twenty-first century in certain parts of Iran. For example, the boy recommends that the meat of a two-month-old kid fed on mother’s milk and cow’s milk marinated with herbs be cooked and served with whey (*kashk*). In Yazd (central Iran), Kerman, and Azerbaijan, *bōzghōrmēh* is still a popular dish. It features chunks of goat’s meat or mutton as a dominant substitute, fried with chopped onions, seasoned with turmeric and cinnamon, sprinkled with tarragon and mint or saffron, and topped by thick yogurt or *kashk*. As for sweets, almond, walnut, and pistachio are used in making delicate cookies, as they were many years ago. A jelly made with quince juice is now called *mōjassamēh-ye beb*. In jams and preserves the peel of *baalang*, a large citrus fruit, is still popular in Fars and Gilan provinces. Quince jam continues to be made in most parts. Cucumber and walnut jams and pickles are remembered recipes in Qazvin.

Other later sources, too, elaborate the sophisticated Sassanid cuisine. An eleventh-century scholar, Tha’alebi of Neishapur, describes in his “History” a variety of dishes including wild birds and other game, fish, lamb, and veal marinated in vinegar, mustard, stock, garlic, dill, and green and black cumin, or in yogurt, flavored with spices, and stewed, broiled, or roasted according to different recipes; barbecued chicken flavored with cane sugar, skewered and grilled; stuffed vine leaves; puddings made of rice, milk, honey, butter, eggs, and rosewater; and delicacies and sweets using countless aromatics. He mentions that peasants marinated their meat in brine and pomegranate juice.

**Festivals.** Festivals were frequent in ancient Persia. For the ancient Persian herdsmen and farmers, the revival of nature in the spring was a terrestrial renewal of life, so people equated the New Year with the spring equinox. Before the equinox, reverence for the seven *Ēmshāspands* (archangels) in the Zoroastrian religion was symbolized in seven cereals and pulses grown in clay pots to predict the quality of the next harvest. In the five leap days (the year being 360 days) preceding *Nōwruz* (New Year’s festival), festivities would begin. Food, including milk and honey, sweetmeats, nuts, and dried fruits, was prepared and bonfires were lit on rooftops to attract the *Farvabars*, or guardian angels of the ancestors, who would descend for the annual reception in which winning and dining continued for five days following *Nōwruz*.

*Yaldā* is still celebrated, marking the birth of Mithra on the longest night of the year. Throughout the long night of *Yaldā*, fresh fruit specially preserved for the oc-

casion, seven kinds of nuts, and a range of dried fruit were consumed in a joyous vigil held to drive out the darkness in anticipation of the sun’s rebirth. Apart from *Mēbrgān* or *Sadēh* little is known of other such festivals.

After the Arab invasion in the seventh century, a great number of Zoroastrians migrated to India, taking with them their culinary culture. However, the art of Persian cookery and the etiquette of eating (*ādāb-e sōfrēh*) at a spread (*sōfrēh*) laden with a colorful array of food survived. These, in later years, highly influenced the Arab, the Ottoman, and the Indian culinary cultures.

In the eighth century, Iranians who helped the Abbasid caliphs gain power passed on the refined Sassanid recipes to Baghdad. This is apparent in a range of cookery books written in Arabic in subsequent centuries.

In the fifteenth century, the haute cuisine that evolved at the Ottoman court was in the style of the Teimurid court of Persia. From the sixteenth century, when a descendant of the Teimurid dynasty in Iran established the Moghul empire in Delhi, the first cookery books, written in Persian and Urdu by Iranian scholars of the imperial court, appeared. In parallel, cookery books were written in Iran by master chefs in the Safavid court and in the nineteenth century in the Qājār court of Nāser od-Dīn Shāh, showing further refinement in the art of cooking, of rice, in particular.

## Modern Iranian Cuisine

**Rice.** Rice in Iran is steamed to a unique perfection, bringing out its full flavor and fragrance, turning the grains into light, fluffy *chēlōw* (plain rice) that may be eaten with *khōrēsh* (stew) or grilled meat (*chēlōw kabāb*). Rice can be steamed with meat, herbs, vegetables, sour cherries, or pulses in many varieties, colors, and mixtures (*pōlōw*) as a crisp crust (*tab-dig*) is formed at the bottom of the cooking vessel. It can be garnished with saffron, barberries, and slivers of orange peel, pistachio, and almond. Rice with beaten eggs, yogurt, and saffron, steamed with layers of cooked meat, eggplant (aubergine), or spinach turns into yet another sumptuous dish known as *tahchin*.

The best rice is grown in the Caspian provinces of Gilān and Māzandarān; it is also cultivated in limited quantity in the Lenjān district of Ēsfahān and along the Qēzēl Ōzan River near Zanjān. The major grades of quality long-grain rice, with their elongated form and characteristic fragrance, Sadri Dōmsīah and Tārōm, are the best known for perfume and taste.

**Stews.** Iranian cuisine in general is the art of cooking the available nutrients in a way that pleases the eye and the palate and balances the functions of the body. Recipes consider food’s properties and elements to formulate an equation in which the ingredients blend harmoniously, each counterbalancing the excess effect of the other on the digestive system.

*Khōrēsh*, derived from the Persian verb *khōrdan* (to eat), is a kind of stew prepared to these rules. The base for every *khōrēsh* is fried onions (garlic is added in the northern and southern regions), meat or poultry, the appropriate spices and seasoning. These are left to simmer in water to a desired consistency, then lightly fried vegetables, herbs, or fruit are added. Depending on vegetables and herbs in season, countless varieties are made all over Iran. For example, chopped mint and parsley would make *khōrēsh-é na'najafari* with celery, or, in the spring, rhubarb, greengages, acanthus, or young green almonds with verjuice (sour grape juice) as seasoning. The famous *khōrēsh-é fēsēnjān*, which turns into a thick light or dark brown sauce, is made of ground walnuts seasoned with pomegranate juice or paste and has a sweet and sour taste. The cooling effect of pomegranate juice balances the warm and rich property of walnuts. This is an autumn and winter *khōrēsh* customarily made with duck, or with chicken or meatballs as substitutes. In late autumn it can be made with ripe walnuts and pomegranate juice. In winter chunks of eggplant or pumpkin, dried prunes, and apricots may be added. It is then called *mōtanjan*. A further derivation is *anār-āvīj* (pomegranate paste or juice and herbs), prepared in the Caspian region. Another speciality is *khōrēsh-é ghōrmēh-sabzi* made with mixed herbs and red kidney beans (in the south, black-eyed beans) with whole dried limes used for fragrance, freshness, and seasoning. Also common is *khōrēsh-e gheimēh* (diced meat) with split peas, served plain or with fried potato sticks and dried lime as seasoning or eggplant, zucchini (courgettes), or celery with sour grapes as seasoning, quinces, or apples with sweetened vinegar as seasoning, etc. A luxury, known from the imperial court of the Qājārs (nineteenth century), is *gheimēh-mōrassa'* (jeweled diced meat), which in place of split peas uses skinned whole pistachios with ample saffron for aroma and color.

**Khōrāk and side dishes.** *Khōrāk*, also derived from the verb *khōrdan* ('to eat') cooked with or without meat, cover an extensive range and reflect the significant contributions of Gīlān and Azerbaijan provinces. Among these dishes are *kabāb*, a variation of charcoal-grilled meat, fowl, or fish; *shāmi*—meat cooked with split peas pounded and kneaded with eggs, ground cumin, and saffron, shaped in a round patty and deep-fried; *kūkū*, a form of thick puffed omelette or soufflé of different vegetables or herbs; *dōlmēh*—stuffed vegetables or vine or cabbage leaves; *tās-kabāb*, meticulously arranged layers of onion, meat, tomatoes, carrots, eggplant, potatoes, and quinces or apples (depending on the season), sprinkled with cardamom and cinnamon, chopped dried lime, and prunes steam-cooked in its own juice on low heat; *kashk-bādem-jān*—fried eggplant topped with *kashk* (whey) and tastefully garnished; *mīrzāghāsēmi*, grilled eggplant cooked with garlic, tomatoes, and eggs. Side dishes are prepared with various vegetables cooked or raw and mixed with yogurt seasoned with aromatic herbs.

**Fish.** Fish is cooked in a variety of ways in the Caspian Sea provinces and alongside the Persian Gulf and the Arabian Sea. In the Khuzistan region well-spiced baked fish seasoned with tamarind is among the specialities whereas in the Caspian area it is barbecued or stuffed with herbs, including dried pomegranate seeds, baked and served with bitter oranges. The Caspian caviar is an important item for export, and the large grey and the rare golden of the Iranian coast are famous among connoisseurs.

**Bread.** Bread or *nān* is revered as a gift from God. Except in the rice-growing areas along the Caspian coast, it is the staple food of Iranians. *Khōrēsh* and *khōrāks* are eaten with *nān* as well as rice. Made in a flat form, the most common varieties of bread are *sangak* (baked on pebbles), *tāftūn*, thin *lavāsh*, thick *barbari*, *nān-é shūrmāl* (dough mixed with milk), and crispy *nān-é rōghani* (dough mixed with butter).

**Soups.** *Āsh* is the general name for a thick soup made with herbs, rice, or pulses with or without meat, served plain or variably seasoned. It is another prominent and universal feature of Iranian cuisine. The recipe for *āsh-e sac* (spinach soup) has been passed down from the Sassanid era. *Āsh* cooked using barley, wheat, or noodles and *kashk* is a convenient dish in tribal life. *Ābgūsh* (literally meat juice) is made with mutton, onions, turmeric, chickpeas, pinto beans, tomatoes, potatoes, and dried lime; the stock is separated and the rest is pounded into a paste. It is the sustaining food of all classes. Other variations of *ābgūsh* are derived from this basic form. Another soup is known as *kallēh-pācheh* (sheep's head and pig's feet in a bouillon); when homemade, tripe is often added. *Halīm* is a homogeneous porridgelike soup made with wheat and pounded meat of lamb, turkey, or goose, garnished with melted butter and powdered cinnamon. *Kūftēh* refers to tiny to very large meatballs in onion-based soup. The *kūftēh tabrīzi* of Azerbaijan is so large that it can hold a chicken, an egg, prunes, barberries, orange peel, and almonds in its center.

There are cold soups for summer. *Ābdūgh*, a soup made from cucumber, raisins, and herbs in diluted yogurt is everybody's meal. *Ēshkanēh*, made with fresh fruit such as sour cherries, is both refreshing and filling.

**Confections and preserves.** A common confection is *hālva*, prepared from flour, butter, diluted sugar, saffron, and rosewater. *Tar hālva*, a sophisticated version of *hālva*, is prepared with ground rice instead of flour and with crushed orange peel or yellow rose petals. Other well-known desserts are *shōllēhzard*, made with rice, water, butter, sugar, saffron, and almond slivers and garnished with cinnamon and crushed pistachio; *masqati*, made with starch, water, sugar, butter, cardamom, and almond slivers; and *yakhdarbēhēsh*, prepared with starch, milk, and sugar. All are perfumed with rosewater or orange-blossom water.

Jams, preserves, *torshis* (pickles), and sherbets (soft and refreshing cold drinks) such as *sērkanagēbin*, made of

sugar water, vinegar, and mint, and others prepared with the juice of rhubarb or various fruits, are prominent features of Iranian culinary culture. The techniques of long conservation of herbs, vegetables, meat, fish, and dairy have been passed on from one generation to another and have been developed in homes mainly by women, the keepers of the household.

**Cookies and pastries.** Cookies and pastries in Iran are generally delicate in form with a subtle aroma, prepared with variation on basic recipes in different regions. *Bāghlava*, made with phyllo pastry, finely ground almonds or pistachio, sugar and light syrup, flavored with cardamom and rosewater, finely cut into small diamond-shaped pieces, is a popular confection. Now commercially produced, it was conventionally a homemade product except in Yazd, where confectioners, as a cherished tradition, have specialized in its production. Similarly, numerous *petit fours*, made with finely ground rice or chickpeas or coconut or almond, are produced. Apart from Yazd, as examples, Esfahān specializes in the production of *gaz* (nugat); Qum in *sōbhān* (a kind of fudge made of germinated wheat, garnished with crushed pistachio); Kermānshāh and Qazvīn in *nān-é bērenji* (rice cookies) and *kāk* or *nān-é yōkbēh* (a fine phyllo made of flour, butter, eggs, and milk, rolled and cut into small pieces, baked and sprayed with powdered sugar); the specialty of Shīrāz is *nōghl* (sugared slivered almond or pistachio, or muskwillow seed). In rural and tribal areas, *kōlūcheh*, a kind of shortbread, is popularly produced, mainly for festivities.

**Street food.** Hot steaming beetroots, grilled pumpkins, baked potatoes, boiled broad beans, and cooked lentils served with powdered Persian marjoram seed sold by peddlers in winter, and liver *kabābs* rolled in flatbread with or without fresh herbs and chopped onions sold all year round are characteristic features of the popular culture. As further examples, a number of puddings and sweetmeats as well as dried barberry or prunella soaked in water for the juice can be added to the list.

Persian food has not reached the international market. Until the early decades of the twentieth century, people holding high functions or the aristocracy saw to their business in the outer quarters of their home. They were fed together with their employees, assistants, and guests by the *kārkhānēh* (workshop), as the kitchen was known in a big household. It was in such kitchens that great chefs trained cooks who specialized in certain branches of cooking and accepted apprentices to ensure the continuity of the tradition.

Commercial sale of food was limited to *qahvēkhāneh* (coffee or, in fact, tea houses), where basic dishes are prepared; *chēlōw-kabābīs*, where only rice and kabobs are served; and certain shops that function only very early in the morning or late in the evening, selling one item like rice pudding, *balīm*, or tripe. Restaurants are a post-World War I phenomenon mainly introduced by Ar-

Modern Iran is famous for its high-quality caviar. This scene is from a caviar cannery in Bandar Pahlavi. © ROGER WOOD/CORBIS.

menian, Caucasian, and Russian émigrés from the former Soviet Union. They introduced their own cookery rather than commercializing the Persian cuisine.

**Feasts and rituals.** Cookies, dried fruit, nuts, and sweets are prepared for *Nōwvrūz* (the New Year festival). The traditional dish for New Year's Eve is *sabzi-pōlōw* (rice with herbs) with fried or smoked fish. On New Year's Day *rēshtēh-pōlōw* (noodles with rice), spiced and artfully garnished, is served. Festivities end with a picnic on the thirteenth day, at which *āsh-é rēshtēh* (noodle soup made with herbs, pulses, and *kashk*) and *bāghēla-pōlōw* (rice steamed with broad beans and dill) are the main features.

Observation of religious mourning is customary during the first ten days of the first month of the lunar Islamic calendar to commemorate the martyrdom of Hossein, the grandson of the prophet Muhammad. The occasion includes offerings in the form of food and puddings to the poor. Rice and *khōrēshs* are served in the evenings. On the tenth day, the well-to-do offer puddings such as *shōllēbzard* or *hālva* to ensure good health for the loved ones. In the month of Ramadan a whole range of sophisticated condiments of fine quality are made available for those fasting and feasting during daylight hours.

**IRON.** Iron is the second most abundant mineral on earth and is an essential nutrient for nearly all organisms. Iron is necessary for many varied functions in mammals, including the synthesis of DNA, the generation of energy from macronutrients by aerobic respiration, and the transport and metabolism of oxygen. Iron is highly reactive and is potentially toxic at high levels of intake; therefore, its utilization and storage present a major challenge for biological systems. Cellular iron exists primarily in its reduced ferrous ( $\text{Fe}^{+2}$ ) and oxidized ferric ( $\text{Fe}^{+3}$ ) states, and conversion of the mineral between these states serves to catalyze many reactions. One example is Fenton's reaction, whereby hydrogen peroxide is converted to highly reactive hydroxyl radicals ( $\cdot\text{OH}$ ).

Both ferric iron and the hydroxyl radicals generated by free iron in this reaction directly damage tissues by randomly inducing DNA strand breaks and by oxidizing and thereby damaging cellular proteins, lipids, metabolic cofactors, and nucleic acids. Therefore, it is not surprising that most iron in the cell is bound or sequestered by proteins, so that the concentration of free iron is very low (usually less than  $1 \times 10^{-18}$  moles per liter). Many iron-binding proteins are enzymes that harness and bring specificity to the reactive properties of iron, whereas other proteins store or transport iron (Table 1). Protein-bound iron can accept electrons during enzyme-catalyzed reactions, enable proteins to recognize and bind substrates, and assist in the formation of defined protein structures.

## Dietary Forms and Factors Affecting Iron Requirements

The Recommended Daily Allowance (RDA) for iron is 8 milligrams per day for men and postmenopausal women and 18 milligrams per day for premenopausal women. Adult males contain about 4 grams of total body iron (50 milligrams per kilogram of body weight), whereas menstruating women contain 40 milligrams per kilogram of body weight. Full-term infants are born with sufficient

iron stores to meet metabolic demands for the first 4 months of life. Breast milk contains 0.2 mg iron/liter; breast-feeding infants receive about 0.27 milligrams per day.

There are two natural dietary forms of iron: (1) inorganic salts of ferric iron, and (2) iron bound to a cyclic carbon ring called heme in the form of hemoglobin and myoglobin in meat products. Inorganic iron is readily liberated from food in the acidic lumen of the stomach but is not absorbed well in the small intestine because of its poor solubility at physiological pH and because it is sequestered by many dietary components that hinder absorption, including phytates, polyphenols, calcium, and fiber. Therefore, only a small percentage of injected iron salts are actually absorbed into the body, thereby indicating that iron salts have a low bioavailability, or ability to be effectively absorbed. However, other low-molecular-weight dietary components bind inorganic iron and facilitate its absorption. These compounds, which include vitamin C and lactic acids, are commonly found in citrus and deciduous fruits and are known as metal chelators. In addition, an unidentified "meat factor" present in animal tissue also enhances the absorption of iron salts. Finally, heme iron has a much greater bioavailability than iron salts because fewer factors interfere with its absorption and it displays greater solubility in water. Hence, heme iron can account for up to 35 percent of absorbed iron in diets when accounting for only 10 percent of total dietary iron intake. In the United States, artificially fortified foods in the form of fortified grain products are a major source of dietary iron and account for nearly 50 percent of all iron consumed.

Iron absorption and transport from the intestinal lumen to the circulatory system is tightly regulated and complex. Enterocyte cells, which are responsible for the uptake and transport of nutrients from the intestinal mucosa, mediate the uptake and transport of iron to the plasma. These cells, once mature, function for only 48 to 72 hours before they are shed and excreted. The capacity of the mature enterocyte to transport inorganic iron is determined very early in its development and is inversely proportional to plasma iron status. The enterocyte iron transport protein, DMT1 (divalent metal transporter), facilitates iron uptake from the intestinal lumen into the enterocyte. DMT1 concentrations at the cell surface are increased when whole-body iron stores are depleted, which increases the rate of cellular iron accumulation into the enterocyte once it is matured. The induction of DMT1 protein synthesis results from increased DMT1 messenger RNA levels. During iron deficiency, the iron regulatory protein (IRP) binds to the 3' untranslated region of the DMT1 messenger RNA and increases its stability. Heme iron is transported into the enterocyte from the intestinal lumen by an unidentified heme iron receptor, and cellular enzymes in the enterocyte release iron from the heme ring. Iron is exported from the basolateral surface of the enterocyte to plasma

by the iron transport protein ferroportin1 (Fp1). Fp1 is believed to assist in the direct transfer of iron to a soluble plasma iron transport protein called transferrin. Transferrin facilitates the delivery of two molecules of iron among the sites of absorption and storage and to all tissues and organs. The transferrin-iron complex enters the cell by binding to a specific protein, the transferrin receptor, which is present on the plasma membrane of all cells. Once transferrin binds to its receptor, the receptor-transferrin complex is engulfed by the cell, forming an internal vesicle called an endosome. Once in the cell, iron is released from transferrin by the acidification of the endosome, and the transferrin receptor is recycled to the cell surface where it can bind additional transferrin molecules.

### Iron Physiology

Intestinal absorption is the primary mechanism that regulates whole body iron concentrations. There are no specific mechanisms to remove excess iron from mammals. Inorganic iron excretion is limited because of its low solubility in aqueous environments and therefore daily iron loss is minimal in the absence of blood loss. Fecal (from shed enterocytes and biliary heme products), urogenital, and integumental losses account for 4 mg/day of iron loss. Menstruation, blood donation, and pregnancy also can cause significant iron loss. Variations in iron status and requirements are influenced by individual genetic makeup as well as by differences in menstrual losses. The latter averages 0.6 mg/day but can greatly exceed that value in the individual, resulting in a need to absorb an additional 3 to 4 mg/day to maintain adequate iron status. An additional 4 to 5 mg/day of iron must be absorbed during pregnancy. States of rapid growth during childhood through adolescence also increase iron requirements.

Most absorbed iron is used by the bone marrow to make hemoglobin, an abundant protein that binds and distributes oxygen throughout the body. The remaining iron is distributed to other tissues where it is incorporated into iron-requiring proteins or stored. Nearly 70 percent of total body iron is present in red blood cells bound to hemoglobin. Another 15 percent is bound to metabolic enzymes and numerous other proteins, including muscle myoglobin, which transports oxygen to the mitochondria, and cytochromes, which act as electron carriers during respiration. The remaining iron is stored in the liver, spleen, and macrophages and can be distributed to other cells during states of dietary iron deficiency. The primary iron storage protein is ferritin, which is a hollow sphere comprised of 24 protein subunits. One ferritin molecule can store about 3,000 ferric iron molecules that can be mobilized readily when required. There are two types of ferritin subunits, heavy-chain and light-chain ferritin. Heavy-chain ferritin sequesters  $\text{Fe}^{+2}$  and oxidizes it to  $\text{Fe}^{+3}$ ; light-chain ferritin aids in the formation of the mineral iron core within the protein. Tissue, gender, hormones, and iron status can

influence the ratio of heavy-chain and light-chain subunits that comprise a ferritin molecule, but the physiological significance of this ratio is not well understood.

### Consequences of Altered Iron Status

Iron deficiency is the most common of all micronutrient deficiencies in the world, and the anemia that results affects an estimated 2 billion people. Dietary iron deficiency results in reduced iron stores in the liver, bone marrow, and spleen, followed by diminished erythropoiesis, which is the production of red blood cells, and anemia, and ultimately results in decreased activity of iron-dependent enzymes. Iron uptake in the intestine is responsive to total body stores such that iron-deficient individuals display increased iron absorption as described above. Clinical manifestations of iron deficiency include impaired endurance exercise due to an inability to deliver oxygen to tissues, microcytic anemia, glossitis, and blue scera. Maternal iron deficiency during pregnancy is associated with several adverse outcomes for the newborn infant, including premature delivery, low birth weight, permanent cognitive deficits, developmental delay, and a wide range of behavioral disturbances. The onset of anemia and depletion of tissue iron concentrations occur concurrently, whereas the other negative consequences of iron deficiency occur after hemoglobin concentrations fall.

The tolerable upper level intake for iron for adults is 45 mg/day; intakes that exceed this level result in gastrointestinal distress. Dietary overload can occur, although it is uncommon, except in individuals with primary hereditary hemochromatosis, an iron-storage disease, which can result in up to fifty-fold increases in storage iron deposits. Hemochromatosis most commonly results from a common genetic mutation or genetic polymorphism in the HFE gene that is prevalent in populations of European descent but can also result from mutations in other iron-related proteins including a transferrin receptor. The HFE protein is involved in intestinal regulation of iron accumulation, but its precise biochemical function is unknown. This genetic disorder, if untreated by regular phlebotomy, results in liver cirrhosis, cardiomyopathy, arthritis, and cancer.

**IRON COOKSTOVE, THE.** The cast-iron cookstove, a constructed range that totally encases the fire, is a relatively recent development in the history of cookery, and an outgrowth of earlier cooking devices made of stone, brick, clay, and tile. The English term "stove" has a history of its own, and has been used for centuries to designate a variety of early cooking devices in which the fire was not enclosed. For example, one precursor to the cookstove involved a raised hearth which, like the later ranges, was waist high, but supported open fires. These, along with structures for partially enclosed fires and portable braziers called stoves, are helpful in tracing the origins of what was to become the nineteenth-century cast-iron cookstove.

### Early History

For thousands of years before the advent of cookstoves, people cooked over open flames. Depending on materials and technologies at hand, various cultures have worked out a cooking surface heated by a fire below. These are exemplified by the Russian domed clay stove and the Japanese *kamado*. Some had holes in the cooking surface to bring cooking pots into direct contact with the flames. Their open fires were easily tended but smoky and somewhat inefficient. More advanced early cultures, among them the Chinese Han Dynasty, used the ceramic *tsao*, a very early range in which the fire was enclosed. The late medieval period and the Renaissance brought many changes because of the greater use of iron. With the growth of cities and consolidation of power, there was a trend toward elaborate cuisines and larger kitchens. Commercial establishments and wealthy or aristocratic households, having more means and more need, were the first to explore various types of "stoves."

The stew stove, one of these cookstove progenitors, was a bank or row of open-top or grill-like "burners," each over its own fire. Its role in the kitchen was as an adjunct to the large roasting fireplaces. For example, the stew stoves of sixteenth-century Italian chef Scappi were made of brick and clay; those of his contemporaries were often made of tile or stone. In such stoves, the fire was not totally enclosed, but they offered individually regulated temperatures and a waist-high surface. In later centuries, this form was sometimes adapted to quantity cookery, using permanently installed large cast-iron or copper kettles, each over their own fireboxes, and used for the preparation of substantial stews and soups. The German architect and engineer Georg Andreas Böckler designed a brick range that followed this principle (Frankfurt, 1666); subsequently others devised cast-iron frames and fireboxes. Like Scappi's stoves, they were usually limited to professional kitchens.

Renaissance ironworkers built on smelting and casting innovations of the medieval period, and developed cast-iron stoves. Böckler's *Furnologia, or: The Art of Domestic Stoves* described such a stove, one that produced coals to be used in a fireplace and another with a hori-

## A BRICK STOVE

Directions for Making Preserves . . . When a chafing-dish cannot be procured, the best substitute is a brick stove with a grating to burn charcoal."

Mary Randolph, *Virginia Housewife*, 1824

zontal surface for household cooking. Subsequently, the English industrial revolution improved blast furnaces, increased production, and popularized iron stoves in both professional and industrial cookery, and in privileged households. For example, Denis Diderot recorded their use by French candy makers in his *Encyclopédie*, 1758.

Northern Europeans (especially Germans and Scandinavians) had stoves early, possibly as a response to their cold winters. In England they were sometimes installed alongside the grate system, used as free-standing ranges, and sometimes employed steam, ultimately developing into the English institution, the AGA stove.

### The American Cookstove

Cookstoves were not new to the colonies: Mary Randolph suggested a brick version (probably a stew stove) in 1824.

By the end of the 1700s early American scientists such as Benjamin Franklin and Count Rumford had worked out further ideas leading to the development of home cookstoves. In the early 1800s New Yorker Jordan Mott manufactured the first American stoves, supplementary adjuncts to the traditional hearth. At first quite small in size, they were placed free-standing in front of the fireplace, their stovepipes carrying the smoke to the fireplace chimney. As they became larger and more complex, they usurped the hearth entirely and were installed directly within the fireplace.

The antebellum period brought many cookstove innovations, among them expanded surface area, multiple lids, dual ovens, warming ovens or shelves, additional storage space, and water boiler shelves. By 1850, most urban middle-class hearths had given way to stoves. The changeover was uneven, slower to reach the lower economic levels and more remote areas.

The cookstove itself demanded new designs for pots and pans. Age-old legs and rounded bottoms, so workable on the hearth, were no longer effective, and were replaced by flat bottoms that could absorb heat by direct contact with the heated surface. A few boiling kettles retained the rounded bottom and short legs (to prevent tipping), and were set into an open lid hole, the hottest setting possible; others were further redesigned with bot-

tom insets that fit down inside the open lid "eye." Trade catalogs of the mid- to late nineteenth century continued to reflect a period of hearth-stove overlap, and supplied cooking utensils for both. With increasing specialization, stovetop equipment expanded to include such adaptations as saucepans, boilers, kettles, skillets, pancake and waffle irons, coffee roasters, toasters, and short-handled utensils.

### How They Worked

The workings and maintenance of cookstoves were demanding. Between the firebox and the chimney, a series of manual dampers and levers controlled the air and smoke flow, the rate of burning, and consequently the cooking temperatures. The fire was lit with all dampers open, after which adjustments redirected the heat and smoke to a passageway surrounding the oven to heat it. As the ovens were without self-regulating thermostats, overheating was prevented by opening oven doors temporarily, cutting down on the fire's air flow. To maintain temperature, the cook checked the relatively small firebox, testing for heat by hand, and stoked it frequently. Such instructions on cookstove management were included in nineteenth-century cookbooks.

Cooking temperatures were also controlled by the position of the pot on the stovetop. The area nearest the firebox was by far the hottest; the farthest corners were the coolest. As the oven was hottest near the wall between the firebox and the oven, one used the farthest side of the oven and turned the pans regularly (rather than positioning the shelves). Cookstoves were notoriously eccentric. A good cook learned their vagaries and adapted.

There was now more choice in fuel. Hardwoods were preferred over soft, as always, as they created more heat and lasted longer. Coal was preferable to wood in that it produced more heat for a longer period of time and was

## HOW TO LIGHT THE STOVE

A fire for cooking purposes is best made in an iron box, or, as it is usually called, a stove, or range.

. . . We control the amount of heat obtained from the fire by dampers in the stove and pipe. . . . Put into the fire-box, first, shavings or loose rolls of newspaper, letting them come close to the front; then fine pine kindlings, arranged crosswise, that the air may circulate freely between the pieces.

Mrs. D. A. Lincoln, *Boston School Kitchen Text-Book*, 1887

easier to procure and handle in urban kitchens, but it triggered debates over possible danger from its fumes.

### General Assessment

Cast-iron cookstoves brought about a major revolution in many aspects of cookery, notably the technology of the kitchen, the character of cuisine, and the role of home cooks.

The new “ranges” influenced cooking technology throughout the Western world. In cultures that had little iron, the designs of cast-iron stoves were applied to newer versions of their earlier traditional stoves. For example, the Russian domed stove evolved into a clay-covered brick bank stove, at first used by the upper classes, and eventually adopted into peasant homes. The Alsatian brick cookstove and the Bavarian stone and tile stove followed a similar pattern.

The attraction of new stoves overcame their shortcomings. Cooks benefited from waist-high, flexible cooking, less bending and lifting, less smoke, and no ash in the food. Their ovens achieved and maintained desired temperatures in far less time, enabling daily baking, and permitted more flexible menus. They heated the house

Cooking with gas is not as new as many people think. This 1884 gas stove advertisement depicts an iron cookstove with all units working at full capacity. ROUGHWOOD COLLECTION.

### THE COAL STOVE

Stoves for coal should be carefully put up, as if the pipe gapes, the coal gas may occasion death.

Catharine Beecher, *Treatise on Domestic Economy*, 1841

Anthracite coal is one of the most difficult fuels for the beginner to manage; but once having learned its requirements, it will be found one of the most satisfactory and constant of friends.

Maria Parloa, *Home Economics*, 1898

You may take the poetry of an open wood fire of the present day, but to me in those early days it was only dismal prose, and I am grateful to have lived in the time of anthracite coal.

*Diary of Mary Bennett*, 1868

more efficiently in winter, and were easily taken apart and reassembled in summer kitchens. However, in comparison with hearth cooking, they did not roast or bake well, were notoriously drafty and finicky, and required arduous cleaning. Some decried the loss of the hearth, declaring that the center of family life was threatened and with it the family itself.

The cookstove had far-reaching effects on cookery and the domestic life of nineteenth-century men and women. Well suited to city life and the growing cash economy, it eliminated the task of producing one's own fuel. Women, now changing their role from farm producer to city consumer, enjoyed the convenience, and

### THOREAU ON STOVES

I used a small cooking-stove for economy . . . but it did not keep fire so well as the open fireplace. Cooking was then, for the most part, no longer a poetic, but merely a chemic process. . . . The stove not only took up room and scented the house, but it concealed the fire, and I felt as if I had lost a companion. You can always see a face in the fire.

Henry David Thoreau, *Walden*, 1846

used their growing discretionary time for philanthropic community welfare. Growing interest in fashionable dining likewise stimulated a far wider range of daily cooking and baking. Simultaneously, a drop in the cost of sugar, flour, and spices led to elaborate home baking, candy making, preserving and canning, and the consumption of snack foods. The gradual development of chemical leaveners, well adapted to the quickly fired cookstove, replaced much yeast baking and encouraged new and revised recipes—especially for quick breads and iced layer cakes.

## ISLAM.

*This entry includes three subentries:*

Shi'a Islam  
 Sunni Islam  
 Sufism

## SHI'ITE ISLAM

Shi'a comprise 10 to 15 percent of the world Muslim population, and are concentrated in the Middle East, particularly in Iran, where Shi'ism is the state religion. Shi'a differ from the majority Sunni Muslims in matters of religious authority and leadership arising from disputes over the legitimate succession to Muhammad, with Shi'a supporting the claim of 'Ali, grandson of the Prophet, and his family and descendants. The teachings of the Qur'an are strictly interpreted and followed. However, the basic pattern of observances, including food-related behavior, is similar for Shi'a and Sunnis.

### Role of Food in Religious Tradition

Islamic food practices are derived first from the Qur'an and secondly from the hadith—the sayings and deeds of Muhammad. Pre-Islamic Arabs had few food prohibitions, and these were more a matter of local custom, specific to particular tribes. The food laws of the Qur'an provided one way of uniting the tribes in common observances, at the same time differentiating the Muslims from the Jews. The use of food to create and maintain boundaries and common identities is common among the world's religions.

Islamic law influences diet by prohibiting or restricting certain foods, based on Jewish dietary laws as mentioned in the Qur'an, and by requiring fasting and feasting at specific times of year. It also enjoins moderation and reasonableness in all things and commends hospitality. Food was strongly linked to hospitality in Arabic cultures and the sharing of food was encouraged by Muhammad as a means of creating common bonds and sharing in common blessings.

Shi'a follow general Qur'anic food regulations. In the Qur'an food is mentioned frequently as a fundamental beneficence, a Divine blessing. Believers are exhorted to eat of the good things with which God has supplied them and are given only minimal dietary restrictions. Forbidden, or *haram*, is that which dies naturally, blood, swine's flesh, and that over which any name other than God's has been invoked. Also prohibited are meat of the ass, of carnivorous animals such as the tiger, fox, dog, and leopard, which kill prey by using their paws, and of birds of prey. Alcohol is forbidden, along with any other substance that is debilitating to the faculties. The meat of permitted animals is only *halal* if slaughtered in accordance with Islamic law, by cutting the throat while pronouncing the words "Bismillah. Allah Akbar" ("I begin with God's name: God is great").

Further food regulations are contained in the hadith and have been elaborated over time by various schools of Islamic jurisprudence. Foods are allocated to one of the five categories of action in Islamic law: obligatory, recommended, neutral, disapproved, or prohibited. Each school of jurisprudence categorizes foods differently, though the differences between Shi'a and Sunnis is, on

the whole, of little practical everyday significance. Foods or parts of animals forbidden based on exclusively Shi'ite hadiths include hare and porcupine, fish without scales, sea creatures with shells (except shrimp is allowed), rabbits, and certain body parts such as the gallbladder and spleen.

Qur'anic food laws are seen as a sign of God's will, but there is no sin in eating prohibited foods in small quantities if essential to sustain life. Sunnis generally permit the consumption of meat slaughtered by Jews or Christians, while Shi'a do so only if necessity dictates. As in all religions, the strictness with which dietary laws and guidelines are observed differs with social status and circumstances, depending on the commitment to practice.

### Fasting

There are different categories of fasting in Islam: those that are obligatory; those that are recommended but which may be broken without penalty; those that are blameworthy and discouraged; and those that are forbidden. Obligatory fasts include the month of Ramadan, expiatory fasts performed as *kaffarah* (atonement) for breaking the Ramadan fast, and those performed in fulfillment of a vow. The chief obligatory fast is Ramadan. Shi'a generally break the fast a few minutes after the sun has set and commence the fast a few minutes before dawn. In both instances the intent is to ensure that the full fasting period is observed. The exemption categories for the fast are similar for Shi'a and Sunnis, though with some variations in interpretation. For Shi'a fasting is not valid if it would cause or aggravate illness or intensify pain or delay recovery; to do so is to cause harm, which is prohibited. Pregnant women in the final trimester and nursing mothers ought to break their fast if there is danger of harm. To continue fasting in such circumstances is not valid. In both instances breaking the fast is optional for Sunnis. Acute hunger, unless life-threatening, is not a sufficient reason for Shi'a to break the fast, but is acceptable to Sunnis. There are other differences relating to travelers, to what precisely breaks the fast, and to what is required in the way of restitution for infractions. The most serious infraction, sexual intercourse with a spouse, is punished with extended fasting and fines in both Shi'ite and Sunni law; such fines include freeing a slave, feeding sixty poor, or fasting for two consecutive months.

Muhurram, the first month of the Muslim year, is a time of major public affirmations of Shi'a beliefs. The one-day fast of Ashura, which falls on the 10th of Muhurram, was, according to Sunni tradition, instituted by Muhammad in imitation of the Jewish practice of marking the deliverance of the children of Israel from the Pharaoh. Although the fast was soon abrogated in favor of Ramadan, it remained as a voluntary observance. For Sunni Muslims Ashura is a joyous festival, commemorated precisely because it is *Sunnah*—the Way of the Prophet. But for Shi'a it is a time of mourning, the anniversary of the murder of Husayn, son of 'Ali and grand-

son of Muhammad, by the Caliph Yazid at the battle of Kerbala. Husayn opposed caliphate rule and was killed in an attempt to restore the imamate. Shi'a mark this occasion with large public parades, at which loud lamentations are accompanied by beating of drums and penitents who scourge themselves with whips or knives. In some places dancers enact scenes from Kerbala and decorated replicas of the martyrs' tombs are carried through the streets. A specific Shi'a practice during Muhurram is the provision of food and drink to the community. In Shi'a neighborhoods children distribute ladles of water to passersby, while tables of food may be set up for the poor. This allows believers to symbolically compensate for the fact that Husayn was allowed to die hungry and thirsty while, at the same time, alleviating the thirst and hunger of the oppressed.

Supererogatory fasts are meritorious for all Muslims on any day when fasting is not specifically forbidden. The first and last Thursdays and the 13th, 14th, and 15th of each month are particularly auspicious, as are a number of other days during the year. It is reprehensible to single out Fridays or Saturdays for fasting, or to fast on Naw Rouz (New Year) or on the day preceding Ramadan. Fasting is forbidden on the first days of 'Id al-fitr and 'Id al-adha. For Shi'a fasting is also forbidden on the 9th of Muhurram, as on this day the enemies of Husayn fasted in preparation for the battle of Kerbala.

### Holidays and Festivals

Shi'a observe the major Islamic festivals of 'Id al-fitr and 'Id al-adha, as well as commemorating many events in the lives of the Imams. 'Id al-fitr is a three-day festival following the Ramadan fast and is celebrated to give thanks to God for providing the strength to complete the fast. It is marked with visiting, gift-giving and preparation, and exchange of favorite foods. Specially prepared sweet dishes are characteristic of the festival, giving it the popular name of Sweet Id. 'Id al-Adha, the feast of sacrifice, is a four-day public holiday occurring at the end of the pilgrimage to Mecca. It celebrates Abraham's complete obedience to God in being willing to sacrifice his son Ishmael, and God's dispensation in allowing Abraham to substitute a sacrificial ram. At public ceremonies the imam sacrifices a sheep for the community. Every Muslim who can afford it should sacrifice at home a goat, lamb, cow, or camel and share the meat with family and friends and with the poor.

'Id al-Ghadir, held on the eighteenth day of the month of pilgrimage, is a Shi'ite feast instituted in 962 C.E. to commemorate the events of Ghadir Khumm, when Shi'a believe that the Prophet designated 'Ali as his successor. This is not observed by Sunnis.

## SUNNI ISLAM

"Islam" comes from the Arabic word meaning 'peace' and 'submission'. For Muslims around the world it is a way of life requiring absolute submission to the will of God. Islam dates from 622 C.E. and is based on the prophetic revelations of Muhammad. From its Middle Eastern roots Islam has spread around the world and, with over a billion followers, is the second largest of the world's religions, after Christianity. About 15 percent of Muslims live in the Arab world and another 25 percent in Africa. Substantial parts of Asia are predominantly Muslim, with Indonesia having the largest Muslim community. There are also significant Muslim populations in Europe and the Americas. The three main Islamic sects are the Sunni, who comprise about 90 percent of all Muslims, Shi'ites, and Sufis. In addition, there are numerous small sects and subsects, such as Ahmaddis, 'Alawites, and Wahhabis, that differ in degrees of orthodoxy and practice.

Although they accept the divine status of the Jewish and Christian revelations, Muslims believe that Muhammad was the "Seal of the Prophets," the last of God's messengers. The word of God as revealed to Muhammad is recorded in the Holy Qur'an, the infallible guide to Muslim conduct. Further guidance is provided by the *sunna*, the authoritative example of the Prophet, whose words and deeds are recorded in the *hadith* (literally 'tiding' or 'information'; more broadly 'every word, deed, and approval attributed to Muhammad'). "Sunni," derived from "sunna," describes allegiance to the ways of the Prophet. Within the Sunni tradition there are four schools of jurisprudence (Hanifis, Malikis, Shafis, Hanbalis) that differ in their interpretations and applications of religious law, including some minor issues related to food.

### Role of Food in Religious Tradition

Prior to the advent of Muhammad, food practices among the Arab peoples of the Middle East were diverse. The establishment of common Islamic food laws united these diverse groups, at the same time differentiating the new religion from Judaism. In several places in the Qur'an, Muhammad refers to the restrictive food laws of the Jews as a burden imposed on them for sins, noting that there were few food restrictions prior to the revelation of the Torah (4:160; 6:146). While he retained certain elements of Jewish food law, such as the prohibition on pork,

Muhammad proclaimed food as a general beneficence, a gift from God to be enjoyed by His people without undue burden. "O ye who believe! Eat of the good things that We have provided you, and be grateful to Allah if it is Him ye worship" (2:172).

Islamic laws regarding food are found particularly in three Qur'anic *suras* (chapters), The Cow (2), The Table (5), and Cattle (6), respectively. In addition, the sayings and actions of Muhammad, as recorded in the *hadith*, provide detailed guidance to acceptable food practices. Food is classified as lawful (*halal*) or unlawful (*haram*). Between these is the category of doubtful or suspect (*mashbooh*). *Halal* signifies food that is acceptable in the sight of God; it includes all food that is not classified as *haram* or *mashbooh*: milk from cows, sheep, camels, and goats, honey, fish, vegetables, fruit, legumes, nuts, and grains. Most animals are *halal*: "Lawful unto you (for food) are all four-footed animals, with the exceptions named" (5:1). However, to be *halal*, meat must come from animals slaughtered ritually in a way (similar to Jewish practice) intended to spare them unnecessary suffering. The words "Bismillah. Allah Akbar" ("I begin with God's name: God is great") are pronounced over the animal as its throat is slit, allowing the blood to drain. In fact, kosher food is generally acceptable to Sunni Muslims: "The food of the People of the Book is lawful for you, and yours is lawful unto them" (5:5). Also, similar to kosher practice, in the marketplace meats and other products are certified *halal* by authoritative Islamic agencies and are stamped with a *halal* seal.

The opposite of *halal* is *haram* food—that which is unacceptable. Pork is the preeminent example of a *haram* food, the only meat specifically forbidden in the Qur'an. Blood, and that which dies naturally (carrion), as well as food over which any other name than God's has been invoked, are *haram* (5:3). Also prohibited in the *hadith* are flesh of the ass, carnivorous animals, such as the tiger, fox, dog, and leopard, which kill prey by using their paws, and birds of prey. Fish must be alive when taken from the sea or river, and only fish that have fins and scales are allowed, which excludes shellfish and eels. Shrimp are generally considered *halal*; however there is some disagreement over this within the Hanafi school of jurisprudence. Land animals without ears, such as frogs and snakes, are prohibited. Foods contaminated by *haram* substances themselves become *haram*. Alcohol is *haram*, along with other mind-altering substances. However, there are several references to wine in the Qur'an that illustrate changing attitudes toward alcohol: wine is acknowledged to have some benefit, but which is outweighed by harm (2:219); believers are exhorted not to pray while under the influence of intoxicants (4:43); and it is expressly prohibited as "an abomination of Satan's handiwork" (5:90). The latter, together with guidance found in the *hadith*, forms the basis for most modern interpretations, which view alcohol as both morally and socially unacceptable. Other intoxicants that cloud the

mind are also forbidden, though this is a gray area. For example, the chewing of *qat* (“khat,” *Catha edulis*), a plant whose leaves contain a mild stimulant, is common in Yemen. Coffee consumption has also been controversial at times, though sixteenth-century attempts to ban it proved impossible to enforce. While coffee is a symbol of hospitality in some Arab countries, it may be avoided by devout Muslims. It is worth noting though that some Muslims, notably Sufis, interpret the Qur’anic verses in other ways and do not prohibit wine. Wine drinking is also acceptable to ‘Alawites, especially in a sacramental context.

If a person is uncertain whether a food is *halal* or *haram*, then it is *mashbooh*—doubtful or suspect—and should be avoided. Ingredients such as emulsifiers, gelatin, and enzymes used in processed foods fall into this category as the animal origin of the constituents may be unknown. Some food manufacturers and Islamic authorities produce lists of foods and ingredients classified as *halal* or *haram* as a guide to food choice.

There are regional, social, familial, and individual variations in the strictness with which food laws are adhered to. Some Chinese Muslims, for example, openly consume pork. Concern for one’s health or obligations stemming from hospitality are reasons for transgressing normative food behaviors. “But if one is forced by necessity [to eat forbidden foods], without wilful disobedience, nor transgressing due limits—then is he guiltless. For Allah is Oft-forgiving Most Merciful” (2:173).

### Fasting and Feasting

Fasting (*sawm*) is one of the Five Pillars of Islam and, as such, is an important religious duty. Muslim fasts require complete abstention from food and drink between the hours of sunrise and sunset. Fasting at different times of year may be obligatory (*wajib*), recommended (*mustahab*), discouraged (*makruh*), or forbidden (*muharam*). The main obligatory fast of the Muslim calendar is that of Ramadan, which lasts for the entire month. Also obligatory is fasting for *kaffarah*—atonement for infractions of the Ramadan fast—and fasts made in fulfillment of vows. Fasting is considered *mustahab* on all days of the year on which it has not been prohibited. It is specifically stressed for the thirteenth, fourteenth, and fifteenth of each month in imitation of the Prophet, and on Mondays and Thursdays. *Asbura* is a one-day fast held on the tenth day of Muhurram, instituted by Muhammad in imitation of the Jewish holiday Pesach (Passover), which marks the delivery of the children of Israel from the Pharaoh. Although *Asbura* was replaced in the second year of Muhammad’s dispensation by Ramadan, it remains as an optional fast.

It is *makruh* to single out Fridays and Saturdays (the Muslim and Jewish Sabbaths) for fasting or to fast on the day preceding Ramadan or on *Naw Rouz*. Fasting is *muharam* on the days of the ‘Id al-Fitr and ‘Id al-Adha festivals. To be valid, fasting must be undertaken with

correct spiritual intent (*niyyah*), which should be renewed each day. Fasting is incumbent on all sane adult Muslims, with exemptions made for pregnant, nursing, and menstruating women, for travelers, and for those in ill health. The exceptions are seen as evidence of the statement that Allah does not want to place an undue burden on His people (2:185). Deliberate infractions of the Ramadan fast are subject to either *kaffarah* (atonement) or *qada* (restitution), though unintentional lapses are not punished. Some differences exist between schools of jurisprudence as to the detailed practices and penalties associated with fasting. For example, Sunnis may break the fast if they suffer acute hunger; Shi’ites may not unless there is risk of illness.

Certain foods have a particular symbolic value because they recall the practices of Muhammad. Thus, fasts are traditionally broken with dates and water, followed by lentil soup and often a salad before the main course, which is more a matter of local custom.

### Holidays and Festivals

During the Ramadan fast Muslims may consume more food than at other times of the year, for Ramadan is an essentially joyous occasion, a time for giving thanks to God. Feasting in the evening is common, and special foods are commonly prepared at family and community meals. Ramadan food specialties vary across Islamic cultures, for example, Syrian *shakreeyeh* (lamb in minty yogurt sauce), Turkish *kaahk Ramazan* (sourdough crescent rolls), and Moroccan *barira* (lamb and lentil stew).

At the close of Ramadan comes the three-day festival of ‘Id al-Fitr, commonly known as “Sweet Id.” The celebration is a way of thanking Allah for providing Muslims with the strength to have fasted successfully, and it is marked with feasting and gift-giving. It is characterized by the serving of sweet dishes, such as *sawaiyan*, a fine vermicelli boiled with milk and sugar. In Malaysia, *ketupat*, rice cooked in coconut leaves, and *rendang*, a spicy beef dish, are prepared especially for this occasion. ‘Id al-Adha, the feast of sacrifice, occurs at the end of the pilgrimage to Mecca. It was previously a four-day festival, now much diminished, in which all adult male Muslims sacrificed a lamb, goat, or cow. Islamic prescriptions require that the sacrificial meat be divided into three equal portions: one for the family, one for friends, relatives, and neighbors, and one for charity. This is in remembrance of God’s mercy in allowing Abraham to sacrifice a ram instead of his son, Ishmael. *Asbura* is a joyous occasion for Sunnis, though it is a solemn historical remembrance for Shi’ites.

## SUFISM

Sufis are members of a small Islamic sect that arose as a protest against the growing worldliness of Muslims after the time of the Prophet. Sufis strive to imitate the words and deeds of Muhammad, and traditionally adopt a life of poverty and abstinence. Although Sufism is firmly anchored in orthodox Islamic doctrine, it emphasizes the inner pursuit of love, obedience, and devotion to God over concern with the outward law or *shari‘a*, and is often associated with mysticism and esotericism. There are hundreds of Sufi orders that have developed within different cultural contexts so that there is no one Sufi way.

### Role of Food in the Sufi Tradition

Sufis are guided by the *adab*, written treatises that prescribe manners or norms of conduct modeled on the life of Muhammad, which includes the food sayings and practices of the Prophet in minute detail. Muhammad praises the virtues of hospitality, generosity, and moderation, and food was and is clearly seen as a means of encouraging these virtues. As an integral part of the daily spiritual life of Sufis, food provides a way of sharing in the greatest of Divine blessings, of creating unity among people and of linking to all creation. Hospitality and eating together were highly commended by Muhammad and, since early times, Sufis have been associated with the serving of food to others. Communal kitchens and guest lodges for feeding the poor and travelers were features of early Sufi settlements, a tradition that continues in Sahas, or Sufi centers where massive concrete tables may serve up to one hundred diners at a sitting. At *moulid* festivals, feeding stations are set up to offer food and drink to passers-by.

### Food Symbolism and Rituals

There is extensive use of food imagery and metaphor in Sufi writings. Sugar and other sweet foods represent the sweetness of piety and community with God, while salt symbolizes purity and incorruptibility. Bread is regarded as sacred in Islam and is treated reverentially. Through the pronouncement of *Bismallah* during the bread-making process, the bread is imbued with spiritual power or *baraka*, which is shared by those who eat the bread. The transformation of the raw wheat to finished bread is used as an analogy for Sufi spiritual development.

Sufi ritual observances (*dhikr*) are concerned with remembrance of God through exaltation and praise. Singing, dancing, and drumming are commonly part of such rituals, as is sharing of food. For example, *ashbura* is a dish that takes its name from the festival celebrated by all followers of Islam. During preparation of the *ashbura*, Mevlevi Sufis stir the pot in a special way while pronouncing the name of God. Sharing the *ashbura* then becomes a way of spreading remembrance of God in the form of bodily nourishment.

## Holidays and Festivals

Sufis observe general Muslim holidays and festivals. *Ashbura* has particular significance for Sufis and Shi‘a. In addition, they celebrate numerous saints’ days, or *moulids*. Major *moulid* festivals attract hundreds of thousands of people and can last for two to three weeks. Sufi orders set up hospitality stations (*kbidamet*) in public buildings, in tents, or simply on cloths spread on the ground. Drink and (usually) food are offered to passers-by, and must be accepted as the food contains the *baraka* of the saint being honored and therefore confers spiritual blessing on the recipient. For the poor, these stations provide an additional opportunity for physical as well as spiritual nourishment.

## Fasting and Feasting

Fasting is an essential feature of Sufism, especially during the forty-day retreat undertaken by initiates in many orders. Early Sufis placed great emphasis on asceticism in the pursuit of self-control and suppression of worldly desires. Eating was seen to be an important source of potential harm to the new initiate, and there are many Sufi stories of extreme restraint. Later, excessive fasting came to be viewed as unfavorably as excessive eating, for the message of the *adab* was one of moderation. Indeed, Muhammad even enjoined His followers to break a fast if invited to eat, for to refuse an invitation to share in God’s blessing was wrong.

## Food and Social Circumstance: Prescriptions and Proscription

While the asceticism of early Sufism has largely disappeared, gluttony is frowned upon and moderation is enjoined. Sufis follow Qur’anic injunctions regarding food and are usually fastidious about observing the prohibition on pork consumption. While many Muslims do eat meat other than pork, Sufi teachings recommend that such meat be consumed only in small quantities. Some orders, both ancient and modern, have praised vegetarianism as a more compassionate practice, and have viewed animal consumption as conducive to animalistic behavior.

## ITALY.

*This entry includes four subentries:*

Northern Italy

Southern Italy

The Italian Meal

Tradition in Italian Cuisine

### NORTHERN ITALY

Northern Italy occupies an area that stretches from the southern Alps south to the Po valley and from the northernmost coast of the Tyrrhenian Sea in Liguria west to the coast of the Adriatic Sea on the northeastern side of Italy. Northern Italian cuisine is distinguished from those of Central, Southern Peninsular, and Insular Italian by the predominant use of butter, cream, cheeses, rice, potatoes, baccalá (dried salted codfish), polenta (corn mush), wines used for cooking, hams, sausages, beef, chicken, and venison, and the occasional use of a much lighter olive oil—produced in limited quantities in the regions of Emilia-Romagna, Veneto, Trentino, and Lombardy—than that of the south.

It is the culinary expression of eight regions where dumplings of all sizes and shapes have been prepared since at least the twelfth century B.C.E. Processed regional foods also include regional meat and fish specialties, such as *Bresaola* (Valle d'Aosta air-dried beef), *Mocetta* (Valle D'Aosta's air-dried mountain goat ham), *Mosciamè* (Ligurian dried filet of tuna and dolphin), *Missoltitt* (Lake Como's sun-dried smelts), *Gianchetti* (blanched baby anchovies), *Ciccioli* (lard-rendered pork scraps), *Speck* (Alto Adige's air-cured bacon), *Mortadella* (baloney from Bologna), and several varieties of *Prosciutto* (air-dried ham).

Northern Italian cuisine favors mild-tasting, creamy, meat-rich, and nutritious dishes inspired by a territory that is an extended vineyard. It has also produced many dishes and specialties that originated with ancient Roman Catholic religious traditions. Besides creating Christmas and Easter specialties such as *Panettone* (Christmas fruitcake), *Colomba* Pasquale (a dove-shaped cake prepared

### BOILED MEAT

Boiled meat was less desirable than roasted meat in many societies. A story told by Marcel Rouff (Hazan, 1980, p. 273) illustrates how one cook overcame this prejudice. Dodin-Bouffant served it to the Prince of Eurasia, who was offended at first to be served such a low-status food, but he soon changed his mind about boiled beef. When Dodin-Bouffant's formidable boiled beef finally arrived—reveled, despised, and an insult to the Prince and all of gastronomy—it was monstrously imposing, borne on a huge platter, and held so high and at arm's length by the head chef that at first the anxious guests were unable to catch a glimpse of it. However, when it was lowered onto the table with straining caution, there were several minutes of stunned silence. Each guest recovered his composure in a characteristic way. Rabaz and Magot inwardly berated themselves for having doubted the Master; Tri-fouille was seized with panic before such genius; Beaubois trembled with emotion. As for the Prince of Eurasia, his reaction wavered among the worthy desire to make a duke of Dodin-Bouffant, as Napoleon had wished to make a duke of Corneille (a seventeenth-century French dramatist); a wild longing to offer the gastronome half of his fortune and his throne if only he would agree to oversee his banquets; annoyance at being taught such an obvious lesson; and impatience to taste the heady enchantments of the culinary marvel set before him.

Judit Katona-Apte

during Easter), *Uovo di Pasqua* (chocolate Easter egg), Northern Italian cuisine also includes dishes that follow Catholic Church mandates regarding food including "no-meat-on-Friday" or "fat and meat during Carnival prior to Lent" with specialties such as *Crostoli* (fried, and sometimes twisted, ribbons of dough), also called *Sfrappole*, *Fritole*, *Chiacchere*, *Lattughe*, *Nastri*, *Grostul*, or *Zeppole*, depending on the regional dialect.

Favorite ingredients of this cuisine are wild foods such as frogs, snails, truffles, mushrooms, and nuts. Typical first-course dishes of Northern Italy include stuffed ring- or square-shaped pasta—tortelli, tortellini, torteloni, ravioli, agnoli, agnolotti, pansotti, capelletti, and capellacci—served either in clear broth or topped with sauces. Northern Italy is also home to gnocchi (finger-sized potato dumplings), lasagna, world-famous cheeses—Gorgonzola, Fontina, Taleggio, Mascarpone, Parmigiano Reggiano, and Grana Padano—and innumerable

varieties of risotto (creamed rice): risotto with truffles (*Risotto con Tartufi*), buds of hops (*Risotto ai Bruscanzoli*), red-and-white chicory (*Risotto al Radicchio*), dandelion (*Risotto coi Brusacoi*), frogs (*Risotto con le Rane*), snails (*Risotto e Lumache*), baby pig tails (*Risotto con Codine di Maiale*), chicken livers (*Risotto con Fegatini di Pollo*), filets of lake perch (*Risotto con Filetti di Pesce Persico*), sausage meat

(*Risotto con Luganega*), peas (*Risi e Bisi*), asparagus (*Risotto e Sparaghi*), artichokes (*Risotto coi Carciofi*), porcini mushrooms (*Risotto ai Funghi*), and squid with its black ink (*Risotto Nero alle Seppie*).

Northern Italian desserts are creamy and rich rather than sweet: *Zuccotto* (Lombardy's cupola-shaped whipped

Polenta maker. From a woodcut printed in Milan about 1860. ROUGHWOOD COLLECTION.

cream and chocolate trifle), *Profiterol* (Lombardy's chocolate-glazed and cream-filled pastry puffs), *Tiramisu* (Venetia and Lombardy's layered zabaglione trifle), *Monte Bianco* (Piedmont's liqueur-flavored chestnut and whipped cream dessert), *Strudel* (Alto Adige's fruit-filled strudel), and *Sbrisolona* (Emilia-Romagna's dry pound cake).

Food portions for Northern Italian meals are small or moderate. What is considered most important is the variety of courses and the type of dishes, not the amount of food. Classic meals are served either with wine or mineral water, which can be sparkling or natural. Over time, multicultural influences from abroad, especially of German, central European, or U.S. origin, have introduced the serving of beer (*birra*) or coke (*coca*) with certain specialties such as *Wuerstel con Crauti* (German sausages with sauerkraut) or pizza. Sweet beverages, sodas, or milk shakes may be graciously tolerated by Italians if they are served by foreigners with classic Northern Italian meals, but they are not recommended according to classic serving standards.

Northern Italy is comprised of several small geographically defined areas distinguished by specialty dishes that feature locally grown and foraged foods.

### The Alpine Range Area

The Alpine Range Area contains portions of northern Piedmont and northern Friuli-Venezia Giulia and the regions of Trentino-Alto Adige and Aosta. In the south, the Alpine Range gradually opens onto a wide valley of well-tended fruit orchards and vineyards and an expanse of farmlands and plains.

**Trentino-Alto Adige.** Three cultural traditions (German, Italian, and Ladin [northern Italian and Swiss]), which at times have clashed politically, have produced a cuisine that offers an array of specialties made with potatoes, cabbage, barley, and rye or other foods procured by hunting or forest foraging. Specialties in Trentino-Alto Adige use snails, chestnuts, wild nuts, wild mushrooms, and meats from domesticated animals. The region's cuisine reflects the taste for wines and *Grappa* (brandy made from distilled grape skins; also regionally called "schnaps"), preserved and air-cured or smoked sausages and meats, slow-cooking stews and soups with barley, freshwater fish from volcanic lakes and glacial streams, lots of sauerkraut, dumplings of all sizes and shapes, dry and long-lasting rye breads, and simple fruit-rich desserts such as Strudel.

Specialty dishes of this region reflect the influences of German and Swiss cuisines and include *Risotto al Teroldego* (rice with red Teroldego wine), *Spezzatino alla Pusterese* (paprika-flavored beef stew), *Tortel di Patate* (potato pancakes), *Torta di Mele* (apple cake), *Carre di Maiale con Crauti* (pork shoulder with sauerkraut), *Pollo al Cren* (stewed chicken in horseradish gravy), and *Camoscio alla Tirolese* (stewed mountain goat Tirolean-style).

**Veneto and Friuli Venezia Giulia.** Both of these northeastern areas of Italy share a border with Austria, and lie near Slovenia and the former Yugoslavia. Both Veneto and Friuli Venezia Giulia are renowned for their vegetables such as radicchio (a red winter lettuce similar to chicory), fennel, and asparagus. Both regions are also famous for their sausages and hams, for example, a prosciutto from San Daniele, as well as a fruity sparkling white wine (*Prosecco di Conegliano*). Venice and Trieste, port cities on the Adriatic Sea, boast a thriving fishing industry.

Specialty dishes of this area reflect both the cultural influences of German and Slavic cuisines and the foods available from the land and sea. Some of the most notable dishes include *Lasagna al Papavero* (lasagna with a poppy seed stuffing), *Suf* (a watery corn mush), *Cialzons* (stuffed pasta pockets), *Verze Impinide* (stuffed cabbage leaves), *Capriolo in Salmi* (stewed deer), *Us in Fonghet* (eggs with porcini mushrooms), *Risotto al Tagio* (rice with eel and shrimp), *Polenta e Osei* (corn mush and roasted birds), *Sardele in Soar* (marinated and fried anchovies),

## PANETTONE

*Panettone* appeared in northern Italy around the fifteenth century. Professional bakers probably developed panettone since the process involved is highly complex and requires facilities and equipment that the home kitchen of the past lacked. As the bread's popularity grew, people began to speculate about its origin. The most popular legend concerns a young Milanese nobleman who fell in love with the daughter of a baker, named Toni. To impress the girl's father, the young man disguised himself as a baker's boy and invented a sweet, wonderful bread of rare delicacy and unusual size with a top shaped like a church dome. This new, fruitcakelike bread enjoyed enormous success, with people coming to the bakery in droves at all hours to purchase the magnificent *Pan de Toni* (Tony's Bread).

*Judit Katona-Apte*

and *Insalata di Radicchio alla Vicentina* (Vicenza-style radicchio salad with bacon dressing).

**Valle d'Aosta and Piemonte (Piedmont).** These regions both fall within the Alpine Range Area and the Piedmont and Lombardy Plain Area, and share borders with France and Switzerland. This geographical proximity is reflected in similar methods of food production and culinary traditions influenced by French and Swiss cuisines. The cooks of Valle d'Aosta and Piemonte, like those of Trentino-Alto Adige, use mushrooms, truffles, berries, and nuts foraged on the southern mountain slopes.

Valle d'Aosta's recipes use *Jambon de Bosses* (cured ham), *Bresaola* (cured beef), *Mocetta* (mountain goat ham), chunky soups topped with mountain cheeses, stews made with game, for example, mountain goat, deer, hare, and pheasant, *lard d'Arnad* (bacon lard), frogs, snails, white and black truffles, fleshy and thorny cardons (or cardoons, relatives of the artichoke), rare ovuli mushrooms (egg-shaped *amanita ovoidea*), celery, cabbage, asparagus, potatoes, carrots, and cold-climate grains—rye, buckwheat, barley, and lots of corn mush (polenta). Piemonte is home to the world-renowned sparkling white wine, Asti Spumante, *Savoardi* (ladyfinger cookies from the province of Savoia), *Gianduiotti* (chocolates made in Turin), and Fontina cheese.

Typical dishes of these regions include *Grissini* (thin bread sticks), *Bagna Cauda* (mixed vegetables with anchovy oil dip), *Griva* (meat loaf wrapped and baked in

pork caul), *Minestra di Riso, Latte, e Castagne* (chestnut chowder with rice), *Tajarin* (very fine ribbon pasta similar to angel hair), *Lumache al Barbera* (snails stewed in red Barbera wine), *Leper alla Vignarola* (hare stewed in wine and grapes), *Rane Rapiene* (stuffed frogs), and *Zabajone* (egg custard with Marsala wine).

## Lombardy

The wealthy, industrialized region of Lombardy is located within the Piedmont and Lombardy Plains Region and shares its eastern border with Switzerland. The cuisine of this region includes lots of rice, plenty of meat, some olive oil, brightly colored, expensive ingredients such as saffron and candied fruit, famous soft cheeses named for the town or area where they originate—Gorgonzola, Taleggio, and Certosa—lake or river fish, and pasta pockets. Lombardy is also famous for its ice cream factories.

Lombardy's specialty recipes feature hearty, one-dish meals: *Buseca* (stewed tripe), *Caseula* (sausages, spare ribs, and ham hocks with stewed cabbage), *Polenta Vuncia* (corn mush with butter, cheese, and sage leaves), *Luc-*

## PORCHETTA

Although eating meat was regarded as disgusting by the upper classes in imperial Rome, pork, along with bread, was distributed among the poor in the streets to maintain order.

*Porchetta*, roast suckling pig, is probably of Etruscan origin, and remains popular in areas that once comprised Etruria. A young pig is deboned, stuffed with a mixture of herbs, salt, and pepper, and roasted whole in a wood-burning oven. There are regional differences in the stuffing: stalks and leaves of wild fennel and garlic in Umbria, wild herbs in the Marches, and rosemary and garlic in Rome. In Sardinia, the dish is called *porceddu* and is flavored with myrtle leaves. While the herbs vary, pepper is its most distinctive spice.

At one time, *porchetta* may have been a mountain food, favored in the winter and prepared primarily for feasts. *Porchetta* has become a regular item at fairs and weekly markets such as *porta portese* (the Sunday morning market) in Rome, where it is sold from the back of trucks or wagons. The slices of *porchetta* are served between the halves of a roll without accompaniments.

Truffle harvesting near Norcia, Umbria, Italy. © OWEN FRANKEN/CORBIS.

*cio in Stufato* (wine-moistened stewed pike), *Laciaditt* (apple fritters), *Cotoletta alla Milanese* (Milan-style breaded veal cutlet), *Frittata di Rane* (a frittata with frog), and *Zuppa alla Pavese* (Pavia-style bread soup with cheese and raw eggs).

### Liguria

Liguria, located in the southern portion of Northern Italy, borders France and touches the Piedmont and Emilia-Romagna areas as well as Tuscany, a region of central Italy. It is a coastal region and its port cities—Genoa, La Spezia, and Imperia—provide its cooks with fish and other varieties of seafood. The copious use of locally produced olive oil is undoubtedly the most notable ingredient in Ligurian cuisine, an element that distinguishes it from the other regional cuisines of Northern Italy. It is used in raw, cooked, and fried dishes, for making pasta sauces with nuts and herbs, for moistening bread, and in desserts.

Ligurian cooking reflects its proximity to the food resources of the Ligurian Sea and the limited agricultural

resources of its geography. Nevertheless, this region has given the world several popular dishes, for example, focaccia (olive oil bread) and pesto (a pasta sauce made of basil, pine nut, and garlic). Seafood common in Ligurian recipes includes breams (*paraghi* and *saraghi*), red mullets (*triglie*), herring (*nasello*), swordfish (*pesce spada*), mussels (*muscoli*), blanched baby anchovies or sardines (*gianchetti*, also called *bianchetti*), and air-dried filets of delfin or tuna (*mosciame*).

Typical Ligurian dishes include *Trofie al pesto* (twisted pasta dumplings with pesto sauce), *Pansoti alla Salsa di Noci* (pasta pockets filled with an herb stuffing and topped with walnut sauce), *Moscardini alla Genovese* (Genoa-style stuffed squid), *Torta di Bietole* (swiss chard quiche), *Stoccafisso in Umido* (dried codfish soaked and then stewed), *Mitili alla Spezzina* (La Spezia-style stuffed mussels), *Castagnaccio* (chestnut-flour cake moistened with olive oil), and several stuffed vegetable dishes, for example, stuffed artichokes or zucchini flowers.

### Emilia-Romagna

Emilia-Romagna, with its eastern coast along the Adriatic Sea, is probably the culinary divide between Northern and Central Italian cuisines. It is centrally located and touches the regions of Piemonte, Lombardy, Veneto, Liguria, Tuscany, and the Marche. In addition to its plentiful seafood resources, which include sole, hake, herring, mullet, turbot, monkfish, grouper, clams, mussels, cuttlefish, and mantis shrimp, Emilia-Romagna is famous for its lasagna, ragu (a meat sauce), meat-filled tortellini, and Parmesan cheese (Parmigiano Reggiano). The city of Modena is well known for its prosciutto, balsamic vinegar, and several sausage specialties, which include *Coppa* (pork sausage), *Pancetta* (pork belly sausage), *Cotechino* (pork meat and rind sausage), *Mortadella*, and *Zampone*, pork leg stuffed with meat and rind. Parma is also famous for its prosciutto.

Typical dishes that incorporate Emilia-Romagna's specialties include *Brodetto* (fish and seafood chowder), *Canocchie Al'olio e Prezzemolo* (shrimp snappers in olive oil and parsley dressing), *Anolini in Brood* (ring-shaped pasta pockets in broth), *Polpettone alla Bolognese* (Bologna-style meat loaf), *Erbazzone all'Emiliana* (Emilia-style quiche of onions and greens), *Cotechino in Galera* (cotechino sausage encased in meat loaf and cooked in red wine), *Asparagi alla Parmigiana* (Parma-style asparagus with Parmesan cheese), *Fagioli e Cotiche* (beans cooked with boiled pork rinds), *Bollito Misto* (mixed boiled meats), and *Lumache alla Piacentina* (Parma-style stewed snails). *Piadina*, a thin, parched, unleavened bread wheel, is also a specialty of this region.

### Parmigiano Reggiano and Grana Padano

No discussion of Northern Italian cuisine can ignore two of its fine cheeses, Parmigiano Reggiano and Grana Padano. Both must be matured very slowly.

Parmigiano Reggiano, usually called Parmesan cheese, has been made regionally since the early thirteenth century and has become a symbol of classic Italian cuisine. It is a semi-fat, hard, flaky cheese made of raw cow's milk, recognizable by its large, wheel-shaped forms, covered by a yellow wax rind, and marked with the dotted brand name, Parmigiano Reggiano. Commonly used as a grated cheese, it has a delicate, fragrant, and unique flavor that it imparts to foods. Under Italian law, Parmigiano Reggiano has a prescribed ripening period, usually about two years. It is produced according to traditional Parmigiano Reggiano methods in plants located in specific areas of Emilia-Romagna, which include Parma and Reggio-Emilia. Other Northern Italian locales that produce Parmigiano Reggiano are Bologna, Mantova, and Modena.

Grana Padano is cooked, cylindrical, semi-fat, hard, grainy cheese. First made at the beginning of the millennium by Cistercian monks in Lombardy, near Chiaravalle, it became known as *grana* (literally, 'grain') due to its grainy consistency. It is commonly used as a table cheese, but, like Parmigiano Reggiano, it is also used as a grated cheese. It is produced in the Po Valley and Delta region in Bologna, Mantova, Asti, Cuneo, Brescia, Como, Cremona, Milan, Trento, Treviso, Venezia, Verona, Ferrara, Piacenza, Ravenna, and other cities throughout the area.

## SOUTHERN ITALY

For the purpose of this entry, southern Italy is defined as Rome and all areas south of Rome (see map). Many ethnic groups, such as the Greeks, Spaniards, and Arabs, have passed through southern Italy over the millennia and influenced its cuisines. Traditionally, southern Italians have been much poorer than their northern counterparts. The poverty of the south has resulted in unique regional cuisines that bear little resemblance to the dairy-based cuisines of the north. Rome, traditionally part of middle Italy, today has a cuisine more southern than northern in temperament.

Interestingly, the ancestors of most Italian Americans are from the South; the dire poverty of southern Italy led to large-scale emigration from regions like Campania, Calabria, and Sicily to the United States. It follows logically that Italian-American cuisine is mainly derived from the cuisines of southern Italy. Pizza, pastas with tomato sauce, organ meats, and eggplant-based dishes are all common components of both southern Italian and Italian-American cuisine. Southern Italy is a historically poor region, and so the population used what they had available—inexpensive ingredients like capers and olives, hot peppers, garlic, and anchovies—to create flavorful and unique dishes. Unlike the northern pastas from regions such as Emilia-Romagna, southern pastas are made without eggs and from harder flour and are often shaped rather than rolled, resulting in a chewier pasta like *orecchiette* ("little ears") from Apulia (Puglia) or *conchiglie* (shells) from Campania. These less-rich pastas need heavier sauces.

In the South there are few cows, so beef, butter, and cream are not part of the diet. The favored cheese is *mozzarella di bufala*, which is made here wholly or largely from buffalo milk (that is, the milk of the water buffalo, not that of the American bison), which has a distinctive taste. There are also goats and sheep—yielding meat and cheeses—and pigs and chickens. Lamb dominates mountain cooking. In the past, young spring lamb was reserved for important occasions such as Easter or weddings and baptisms, but today it is more common and often available year-round. Near the coasts, saltwater fish such as *spigola* (sea bass), *orata* (bream), and *dentice* (dentex, a fish

related to the porgy), as well as a variety of shellfish and cuttlefish, are available.

Olive oil is produced around the Apennines and in southern Apulia, and is used all over the South. Suitable soil and temperature contribute to an abundance of vegetables and fruits, and many types of herbs are also produced. Eggplant is a major food item, as it grows better in the South than in the North and can be prepared in many different ways; *melanzana*, the Italian word for eggplant, derives from *mela insana* (“noxious apple”).

Rome, Naples, and Sicily are places that non-Italians are familiar with; however, there are other regions in Southern Italy, and some of their food culture is also described here.

## Rome

Rome is truly the Eternal City. Its rich and fascinating history includes the elaborate public and private feasts held by ancient Roman emperors. That said, modern Roman cuisine is actually quite simple and much influenced by other regions. Dishes are prepared simply with a few inexpensive ingredients. Antipasti are not elaborate, pasta sauces are quick to prepare, and there is a large variety of vegetables (especially leafy greens).

Historically, Rome was the place where cattle were butchered, and so Romans are famous for their use of the *quinto quarto*, or fifth quarter, the organ meats and parts of the cattle that were left over after butchering. Two famous Roman dishes, *coda alla vaccinara*, a stew of oxtail braised for a long time with celery, carrots, onions, tomatoes, herbs, and spices in white wine, and *rigatoni alla pajata* or *pagliata*, short, tubular pasta with beef or veal intestines in a tomato sauce, were born around the communal slaughterhouse in Testaccio.

A popular meat is lamb, which is usually roasted in the oven (*abbacchio al forno*) and served with potatoes. Examples of other meat dishes considered very Roman are *pollo alla Romana*, chicken with red and yellow peppers; *saltimbocca alla Romana* (literally, jump into the mouth) made of thin slices of veal, prosciutto, and sage; and *trippa alla Romana*, which is tripe in a tomato and mint sauce.

*Bucatini all'amatriciana* (tubular pasta with bacon and tomato sauce) originated from country kitchens, where bacon, olive oil, and fresh tomatoes were plentiful. Fettuccine Alfredo is just *pasta al burro* (pasta with butter) from Alfredo's restaurant in Rome. Some other popular pasta sauces are *cacio e pepe* (pecorino cheese and pepper), *carbonara* (bacon, eggs, and pecorino and Parmesan cheeses) and *arrabbiata* (hot pepper and tomatoes). *Gnocchi alla Romana* are dumplings made of semolina, eggs, milk, and cheese. *Spaghetti alla puttanesca* (literally, spaghetti whore-style) is made with olives, anchovies, and capers.

There are also soups, all with some version of pasta in them, such as *stracciatelle* (literally, “little rags”), so named from the thin batter of egg, flour, and Parmesan that is poured into the chicken or beef broth used. Oth-

ers feature herbs, such as lentil soup flavored with *nepitella* (wild mint) and bean soup flavored with rosemary. There are also *minestra de ceci e pasta* (soup with chickpeas and pasta) and *zuppa di arzilla* (fish soup).

Romans say it takes four people to make a proper salad: a spendthrift for the oil, a miser for the vinegar, a wise man for seasoning, and a madman for mixing. *Panzanella* is bread salad with tomatoes, cucumbers, onion, basil, and dressing. A classic Roman winter salad is *puntarelle*, shoots of a particular variety of chicory with a bitter undertone, tossed with a dressing made with olive oil, anchovies, garlic, and lemon juice. Some salads are a mix of greens sometimes called *misticanza*, preferably with the addition of *rughetta* (also called *rucola*, *rocola*, and, as it is in English, *arugula*). More recently tomatoes, shredded carrots, and even canned maize (corn) may be added to salads.

Artichokes are also seasonal and popular as in *carciofi alla Romana* (Roman style), which are stood upright in a pan as they cook with garlic, mint, parsley, and an abundant drizzle of olive oil. Another famous preparation is made from *romanesco* artichokes, which are round and lack a spiny choke. These reach gastronomic heights when prepared *alla giudia* (Jewish style), in which the artichokes are flattened and deep-fried to look like golden sunflowers and their leaves have a delicious nutty crunchiness. This dish has contributed to the fame of the restaurants in the Roman ghetto.

Also popular in Rome are such stuffed vegetables as tomatoes stuffed with rice and mozzarella, or zucchini stuffed with chopped meat. Then there are vegetables, mainly greens, that are prepared *all'agro* (with a lemon-juice dressing) or *in padella* (stir-fried).

Rome is partial to frying: *fritto misto* (mixed fry) can contain shrimp and *calamari* (squid); or artichoke and brain; or different cheeses; or a mixture of vegetables; or *suppli al telefono*, a croquette of rice with mozzarella cheese in the middle—when one bites into it the mozzarella flows out in long threads, as in a telephone cord. The famous *fiori di zucca* (zucchini flowers) are stuffed with mozzarella and anchovy and dipped in batter before frying. Cod is also batter-dipped and fried (*baccalà filetti*).

*Pecorino romano* and ricotta are the most favored cheeses. Ricotta, a soft sheep's milk cheese, is prepared inside wicker baskets.

*Rosette* (hollow, very crisp rolls) are very characteristic of Rome, as is *casareccio*, a chewy, peasant-style bread.

Favorite desserts in Rome are fresh fruits, especially strawberries from Nemi (a town on the outskirts of Rome), or *macedonia* (fruit salad). Many other popular desserts have originated elsewhere, such as *tiramisu* (literally, “pick me up”), made of mascarpone (a very creamy, soft cheese, typically made from cow's milk), ladyfingers, coffee, and other ingredients specific to the home or restaurant; *torta de la nonna* (cake with custard and pine

nuts); *panna cotta* (boiled cream), served with a variety of toppings, such as berries, chocolate, and caramel; *profiteroles* (mounds of little cream puffs drizzled with chocolate); and *gelato* (ice cream) in flavors such as lemon, coconut, orange, and pineapple, frozen and served in a container made of the skin or shell of its source.

Examples of foods reserved for specific festive occasions in Rome are lentils with *cotechino* and *zampone* (varieties of pork sausage), served on New Year's Eve; *porchetta* (roast stuffed pork), traditional at the festival of Noantri in Trastevere; *pan giallo*, a fruit-and-nut cake served at Christmas; *bigne di Giuseppe* (fried doughnuts), filled with cream or chocolate eaten for Father's Day; and *maritozzi* (raisin buns), traditional for Lent.

## Campania and Naples

Naples has long guided the gastronomy of the region and its cooking has had the most influence on the way non-Italians regard Italian food. It is said that the true Neapolitan is poor, but likes to eat well and is proud of the invention of three of the tastiest food items: pizza, tomato sauce, and macaroni. Poor immigrants exported Neapolitan cuisine, rich in tomato sauce, garlic, olive oil, and black olives, to the United States and elsewhere. As meat and seafood were out of reach for the poor at home, the transported cuisine used more meat but fewer vegetables; the classic Italian-American dish, spaghetti with meatballs, for example, is not common in Italy. Immigrants also used more garlic and oregano.

But Naples was a kingdom that in the households of the nobility also had a refined cuisine that required extensive effort; a simple *ragù* (sauce), for example, took many hours to prepare. The master of the kitchen of the noble palaces was the *monzu* (a term derived from the French *monsieur*), a combination of cook and artist, revered and respected by all. He was responsible for the preparation of elaborate and rich court cuisine with dishes like *braciolla* (stuffed beef roll), *mozzarella in carozza* (fried mozzarella sandwich), and *timballi* of pasta or rice with eggplant, cheese, and tomato. Desserts like *baba* (a cake made of yeast dough with syrup) and *sfogliatelle* (literally, "little sheets"—flaky pastry wrapped around sweet items) were lavish and unusual. *Spumone*, an ice-cream confection in strips of colors, is also native to Naples.

The cuisine of Campania and of Naples is rich in vegetables and pasta, often layered in casserole dishes. But the Neapolitans also prepare refined seafood dishes such as *zuppa di vongole* (clam soup), or spaghetti *con le vongole in salsa bianca* (with clams in white sauce), or *cozze in culla* (tomatoes stuffed with mussels and a mixture of capers, chopped parsley, oregano, and bread crumbs). A Neapolitan dish still eaten at home is *minestra marinata*, made with pork fat and boiled greens. The richness of the soup depends on the economic conditions of the family; this was the basic daily meal until the arrival of pasta.

The people of Naples were the first to accept the tomato from the New World, at a time when other Europeans believed it to be poisonous.

Arguably, Naples's biggest contribution to world cuisine is pizza. Royalty played an important role in the development of pizza: For example, *pizza Margherita* reflects the three colors in the Italian flag (basil for green, cheese for white, and tomato for red) and was created specifically for King Umberto I's consort, Queen Margherita. Queen Maria Carolina, the moody and autocratic wife of King Ferdinando I of Naples, offered pizza to her entire court.

In the towns of Campania, including Naples, life takes place in the streets. In the working-class districts of Naples, the streets seem to consist of one long outdoor food shop. This tradition has roots in the past when people spent most of their days outdoors. Housing was cramped and uncomfortable, but the weather was warm, very conducive to outdoor living. Even today, one can observe that people spend much time in bars or in piazzas or just sitting on chairs in front of their doors. Until 1800, all kinds of food were eaten outdoors, including macaroni, pizza, and seafood. There was the macaroni vendor, for instance, who scooped out pasta from huge cauldrons and for a few pennies more offered it with tomato sauce or with boiled *polpi* (octopuses) served in a cup with their steaming fragrant broth.

## Sicily

Sicily, the Mediterranean island in the sun, close to North Africa, enjoys strong Greek and Arab influences. Its cuisine, specifically its cooking style, has influenced the food culture of Italy and of other parts of the world. On the eastern side of the island, the cuisine is sober and mild, avoids sweet and sour tastes, and is less generous with sugar in sauces; whereas in the western part of Sicily, the influence is Saracen, with strong contrasts and flavors. It is thus not surprising that one of the specialties of Trapani, a seaport in northwestern Sicily, is *cuscusu* (couscous).

The dish more people associate with the island than any other is caponata, a cooked eggplant delight consumed cold and made with a number of ingredients such as celery, capers, anchovies, chilies, olives, tomatoes, and vinegar. It comes in many varieties; some are purely vegetarian, whereas the Palermo version can also contain fish.

Eggplant dishes are definitely favored in Sicily, as are tomatoes and pasta. Pasta varieties are abundant and are often baked into *timballi* (timbales); the most famous of these is *timballo di anellini*, made with ring-shaped dried pasta, *balsamello* (béchamel sauce), ground beef, chicken, peas, and vegetables, all wrapped in lettuce leaves and baked in a mold. A local specialty is spaghetti *con sarde* (with sardines), often prepared with raisins and nuts as well. Sicilian pizza is usually thicker than other varieties,

and has anchovies. The fish of the Adriatic Sea are different from those of the Tyrrhenian Sea, and in Sicily there are swordfish from the warm water.

Sicilian cuisine has its own terminology: *arancini* (literally, little oranges) are fried balls of rice, meat, and grated cheese; *quaglie* (quails) are eggplants sliced open and fried in oil; and *falsemagne* (false thins) are meatballs made with salami, hard-boiled eggs, parsley, and other ingredients. Eggplant dishes are often given the appellation *Norma*, as in spaghetti *alla Norma*.

The cheese-making tradition in Sicily is very important. Cheese is a nourishing food that can be processed at the household level and is easily transported and preserved. That is the reason for the heavy reliance on cheese by poor people. Some of the favorites are *pecorino Siciliano*, a cheese with a hard consistency that is made from the ewe's milk and is aged and salted; *Ragusano*, a pear-shaped cheese made from cow's milk, which received its name from the practice of suspending the cheese from a beam with a cord; *caciocavallo Palermitano*, similar to Ragusano but having a pungent odor and a piquant flavor due to the type of grass eaten by the cows; *tuma*, pecorino before it has been salted; and *primosale*, salted only once (*provola* is a smoked version).

Ricotta is made from fresh ewe's milk and is extensively used in Sicilian cooking. Salted and baked ricotta cheeses have been developed in response to the need to preserve them. *Canestrato* owes its name to the pattern created by the wicker baskets in which it is pressed. It is made from ewe's or cow's milk and probably originated from attempts to make pecorino, for which it can be substituted in cooking.

Sicily exceeds all the other regions of Italy in its abundance of sweets, fruits, and ice creams. Candied fruits, sweets made with almond paste, and ice cream are available everywhere. *Cassata* (brick-shaped sponge cake filled with ricotta, candied fruit, and marzipan) may be the most famous of Sicilian desserts. Many of the recipes for Sicilian sweets come from monasteries, and until the turn of the twentieth century their entire production went to the clergy and to Sicily's aristocrats. Some recipes remain a mystery: the nuns of Santo Spirito, for example, refuse to reveal their secrets for making the sweet dessert they sell at their convent in Agrigento, or at the orphanage in Erice. Fortunately, these traditional sweets live on during the religious festivals such as Easter, when desserts made from almond paste in the form of fruits, sheep, and patron saints are sold.

## Apulia

Apulia is a region in southeasternmost Italy producing wheat and a variety of vegetables—tomatoes, artichokes, lettuce, fennel, peppers, and onions—citrus fruits, olives, almonds, figs (some dried with almond flavoring), and grapes. Add to this a sea full of fish, as well as fields for grazing, and the result is a variety of ingredients that can easily be combined into a sumptuous cuisine.

Homemade pasta is found in unusual shapes like the *orecchiette* traditionally paired with broccoli rabe, or *cavatelli* (literally, little plugs). For Sunday dinner a favorite is *maccheroni al forno* (baked macaroni), a pie filled with little meatballs, sliced hard-boiled eggs, pieces of artichoke, salami, and cheese. *Ciceri e tria* is composed of fried pasta strips with chickpeas.

Since the sea surrounds three-quarters of the area of Apulia, seafood products are abundant and popular. Sea turtle, oysters, mussels, cuttlefish, and octopus are cooked in simple ways, sometimes even eaten raw in the markets. The dominant meat is lamb, roasted, stewed, or even fried. *Gniumerieddi* are lamb innards cooked with pecorino cheese. Beef is used for either meat sauce or small meatballs, possibly because in poorer times the only cattle to be slaughtered were old and produced tough steaks.

Due to the popularity of lamb and the enormous flocks, cheese made from sheep's milk is very popular, including fresh ricotta and pecorino. A typical snack of this region is the *calzone* (literally, big sock), pizza dough spread with onions, black olives, capers, tomatoes, pecorino cheese, anchovies, and parsley; closed and pinched around the edges; and baked in the oven.

Homegrown yellow and white melons, sweet watermelons and grapes, and *cotognata*, a quince concentrate, are considered appropriate choices for ending a meal.

## Abruzzi e Molise

Most of the great cooks of Italy come from the region of Abruzzi, where the fame of the local cooks, who were often highly sought-after by nobles living in other parts of the kingdom, began in the sixteenth century. This geographical area is known for strong flavors: *peperoncino* (hot red pepper) is used to flavor many dishes, and a favorite sauce for pasta is *aglio, olio e peperoncino* (garlic, olive oil, and hot red pepper), which can be heavy going for those not accustomed to spicy food. *Alla chitarra* (guitar-style) is a well-known pasta named after the utensil used for cutting it.

Ideally, the cuisine of Abruzzi is divided between that of the sea and that of the mountains. The first has the classic *brodetto* (fish stew of many different fish) as a principal dish. Other dishes include fried fish and fish in sauces served with pasta, as well as freshwater fish, such as mountain trout and river shrimp. Lamb is the popular meat: *agnello all'arrabbiata* (literally, angry lamb) is a favored spicy entrée. *Pizza sette occhi* is a dessert in which the pastry strips resemble seven eyes.

Among the unique dishes of Molise is *p'lenta d'iragn*, a white polenta made with potatoes and wheat, and served with tomato sauce. *Scamorza* (a cheese similar to mozzarella) is a popular item from the region and is usually served grilled.

## Basilicata and Calabria

Basilicata is known for spicy cuisine: as its inhabitants were poor, they made their fare more interesting with

the use of spices, such as ginger. Sausages in some parts of northern Italy are still called by an old name for Basilicata (*lucania* or *licanica* or *luganega*), and so are some pasta dishes, such as *cavatelli alla lucana* with mushroom and sausage, or *cavateglie e patate*, pasta and potatoes with a ragù of rabbit and pork. Pasta dishes are often named after towns, such as *orecchiette alla Materana* (a town in Basilicata), which has a sauce made of vegetables and arugula. Other pasta dishes are frequently served *all'arrabbiata*.

In Calabria, pizza is called *pitta* (flat) and is served without tomatoes; *ciambotta* (big mixture) is a vegetable stew of eggplant, potatoes, tomatoes, and onions; *morseddu* (little morsel) is a traditional breakfast dish of pork-tripe stew with liver and herbs served in a pitta; *licurdia* is onion-and-potato soup; and *millecosedde* (thousand things) is a soup of dried beans and vegetables with pasta.

### THE ITALIAN MEAL

Meals are a central part of Italian family life. Italians are passionate about food and eating, and much of their socializing is done around the sharing of meals. As with most cultures, there are specific dishes associated with specific Italian holidays. Unlike many Western societies, however, Italians have not embraced a multitude of foreign and ethnic ingredients. Although Italian cities have many more foreign and fast-food restaurants than they did ten years ago, most Italian restaurants—and indeed most homes as well—take a more traditional and conservative approach to meals. “Fusion” and “nouvelle cuisine” are not terms commonly associated with Italian meals.

Fast food is popular with the young. Eating fast food is more a social than a culinary experience, and signifies conformity to a peer group, an identity independent of one’s household, modernity versus tradition, and being in the company of, and behaving according to the rules of, chosen friends as opposed to family.

Due to Italian attention to tradition, there are reactions. Movements such as *il ricupero* (the retrieval) and *la riscoperta* (the rediscovery) are founded to maintain tradition in the modern world. The best-known such initiative is the “slow-food movement” that began in Italy in 1986 to challenge “fast food,” which was believed to harm health, destroy the environment, and wipe out traditional cuisine. By 1999, thirty Italian towns had designated themselves “Slow Cities,” where regional tradition in food, parks, and similar values are emphasized over traffic, neon signs, noise, and fast-food chains.

### Shopping and Meal Preparation

The traditional Italian housewife shopped daily. Her morning visit to the open-air market was a form of ritual. In separate stalls she would purchase fruits and vegetables, fish or meat, eggs, cheese, and *salumi* (cold cuts), depending upon what was in season and what she needed. If she needed something more in the afternoon, she could pop out to the *latteria* for fresh milk, the *alimentari* (grocery store) for bread, cold cuts, cheese, and packaged foods, the *macelleria* for meat, or the *frutteria* for fruits and vegetables. These small family-owned stores populated every neighborhood. Today, however, things are changing. Supermarkets, especially the megastores, are rapidly replacing small neighborhood shops.

The designation of housewife (though she is likely to be a working woman) above is deliberate, for in traditional Italian society gender roles are closely associated with food preparation. In the home, women are responsible for meals. Men may cook occasionally or prepare a specific dish, but the responsibility for daily cooking rests with women.

### Eating Out

Average Italians do not socialize in their homes with friends and acquaintances; meals at home are usually shared with family members. Eating in restaurants with family, friends, and business associates is quite common. On weekends it is not unusual to see extended families of four generations eating at a large table. There are many different types of eating places, as described below.

A *ristorante* is traditionally a proper restaurant. *Ristoranti* have attractive table settings, starched tablecloths and napkins, and numerous choices for every course. To be a waiter is a career opportunity, and many stay with the same restaurant for a lifetime. Female waiters are still infrequent but are increasing in number.

A *trattoria* is a small eatery with a limited menu. An *osteria* is a less sophisticated eating place frequented by neighborhood people, with a few characteristic dishes. Both are simple, family-run operations, in which people often sit at common tables, large sheets of butcher paper under their plates. A pizzeria is an eating establishment specializing in pizza. Some serve only pizza, salads, and antipasti (appetizers), while others also serve pasta dishes and a limited choice of meat dishes.

An *enoteca* is distinguished by its large selection of wine; a limited selection of dishes is served there, usually comprising cold salads and other appetizers. Recently, many have started serving a limited menu of hot foods. A *tavola calda* (snack bar serving hot food, often cafeteria-style) is not considered a restaurant and is used for quick snacks, usually at lunchtime. A *rosticceria* (roisserie or grill) sells ready-to-eat foods such as grilled chicken, pizza by the slice, roasted potatoes, cooked vegetables, and some baked-pasta dishes to take home. Some of these distinctions are disappearing in the modern world; it is chic today to call a restaurant a *trattoria* or *osteria*, and *enoteche* have become popular eating places.

**Coffee Bars.** Bars serving mainly coffee during the day are a very important part of Italian social life. The number of ways Italians drink coffee seems to be endless: *espresso* (small but strong), *cappuccino* (espresso with steamed milk), *lungo* (with extra steam), *ristretto* (very strong), *caffè latte* (with much hot milk), *macchiato* (spotted with milk), *corretto* (with a shot of brandy or grappa), *doppio* (double), and *caffè Haag* (decaffeinated), to mention just a few. Romans claim that the quality of the coffee is determined by the three Ms: *Mano*, *Macchina*, and *Miscela* (hand, machine, and mixture). Italians drink their espresso quickly, unlike other Europeans, who sip it for a long time. Bars also serve fruit juices (*spremuta* or *sugo*), as well as *gelato* (ice cream), *granita* (flavored ices), and, recently, iced tea during the hot season.

People gather in bars to have a drink and a snack. They stand at the counter and read the newspaper. As Italians are avid soccer aficionados, they are likely to be loudly discussing last night's game. Bars that have tables, especially outside, charge extra for sitting at them.

### Food Events

Historically, Italians had their major meal, or *pasto*, in the middle of the day, and then rested. Workers would go home to eat and return to the workplace in the afternoon. Today, distances are greater and more people work away from home, and so in many households, *pranzo*, the main meal, is now eaten in the evening. The exception is the Sunday midday meal, considered by many to be the most important meal of the week. On Sunday afternoons (often post-Mass), extended families will gather for large, lengthy multicourse meals.

Breakfast, *piccola colazione* or *prima colazione*, is not a major meal for most Italians. It is usually taken at a bar and includes coffee (often cappuccino) with a pastry such as a *cornetto*, the Italian equivalent of a croissant. There are many types of *cornetti*: plain, or filled with chocolate, cream of rice, jam (called *marmellata*), or custard. Other popular pastries are the brioche and the doughnut.

### Structure of a Meal

Most people, when they think of an Italian meal, think of pasta. And while an Italian meal is much more than

that, it is indeed the pasta (or at any rate the pasta course) that sets the Italian meal apart. The common American or European practice of serving stews and braises over noodles, rice, or dumplings is not found in Italy. Instead, these starches are served on their own, as a separate course. (The exception is potatoes, which are considered a vegetable, not a starch, and are often served with grilled meats.) Normally, the starch course will be prepared with its own separate sauce, though in the home the starch may be served with the sauce from a stewed or braised dish, followed by the meat from the same dish as a second course.

At first glance, a meal in Italy appears strictly structured. The traditional meal contains at least four courses: the antipasto; the *primo* (first course) of pasta, rice, polenta, or soup; the *secondo* (second course) of meat or fish; and the *dolce* (dessert). However, these multicourse meals are no longer daily occurrences for most Italians. At home, they may have just one or two courses for dinner, and the order of these limited courses contains some flexibility. While the *primo* would never follow the *secondo* (as is obvious from the names), Italians will eat meals of antipasto followed by *primo*; or *primo* followed by antipasto; or, less commonly, antipasto followed by *secondo*, or *secondo* served with selected antipasti on the side. They will not, however, eat two dishes that are considered *primo* together, such as soup followed by pasta, a sequence common in central European meals but shunned by Italians.

Despite eating fewer courses at home, Italians tend to regard eating out as an occasion for a more traditional three- or four-course meal. Bread, wine, and water accompany all meals (except, of course, breakfast), no matter how many courses are served.

### Antipasti

Formal meals start with antipasti. There is tremendous range and regional variation, and in many situations an antipasto could be considered an elaborate meal by itself.

There are several bread-based preparations that may be included with an antipasto. Most typical are *bruschetta* (known in Tuscany as *fett'unta*)—toasted or grilled bread rubbed with garlic and drizzled with fruity olive oil (chopped tomatoes or other toppings can also be added); and *crostini*, thin slices of toast covered with an assortment of pastes made from chicken livers, mushrooms, truffles, artichokes, olives, bone marrow, and so forth.

One may find any or all of the following on an antipasto table: marinated cold vegetables such as eggplant, zucchini, whole small onions, and peppers; boiled greens such as spinach, *cicoria* (chicory), and broccoli rabe; anchovies, seafood salad, and mushrooms marinated in olive oil; frittatas (unfolded filled omelettes); *affettato* (cold cuts) of cured meats such as salami, prosciutto, mortadella, smoked tongue, and sausage.

There are also cheeses, especially mozzarella, Parmesan, and pecorino. The favored cheese is *mozzarella di*

*bufala*, which is made at least partly from buffalo milk (that is, the milk of the water buffalo, not that of the American bison) and has a distinctive taste. Some popular cold antipasti are not on the buffet but can be ordered from the menu. Perhaps the most famous example of this is prosciutto and melon (or in season, figs). Other popular ordered antipasti are carpaccio (very thin slices of raw beef or fish), and *bresaola* (cured air-dried beef) drizzled with olive oil.

Antipasti can also be fried and served warm. *Crocchette* (croquettes) are popular; one type is *suppli* (rice balls filled with cheese or ground meat, dredged in breadcrumbs, and fried). There are olive *ascolane* (fried stuffed olives), *baccalà filetti* (dried salt cod, fileted and fried), and vegetables dipped in batter and fried. The famous *fiore di zucca* (zucchini flowers) are stuffed with mozzarella and anchovies before being dipped in batter for frying.

### Primo

*Primi piatti* or just *primi* are felt to constitute the first course of an Italian meal, though they follow the antipasti. This course includes either pasta, rice, gnocchi, or polenta with sauce, or soups containing pasta, rice, or *farro* (spelt—an ancient variety of wheat).

**Pasta et al.** The variety of pasta shapes and sauces is seemingly infinite. Regions and even villages often have their own specific creations. A few examples are offered here.

It is important for Italians to match the shape of the pasta with the sauce, though they allow much flexibility. Certain pastas are always mentioned within the context of a sauce, such as *bucatini all'amatriciana* (tubular pasta with a tomato and bacon sauce), or *fettuccine all'Alfredo* (fresh egg noodles with butter, cream, and Parmesan), or *spaghetti alla carbonara* (spaghetti with bacon, eggs, cheese, and pepper); but substitutions can be made. At restaurants, waiters recite what is available by the shape of pasta—penne, spaghetti, fettuccine—and expect the customer to state what sauce should go on it. While almost any combination is possible, there are “rules.” One general rule is that smooth sauces are appropriate on long pasta, and sauces with chunks of vegetables or meats are better on small pasta shapes, which trap the chunks. Another is that fresh egg pastas work better with butter-based sauces than olive oil-based ones. In the dairy-rich north of Italy, fresh egg pastas are very popular, whereas in the olive oil-dominated south, dried or eggless pastas predominate. An important “rule” is that all pastas are consumed without a spoon (that is, with just a fork), even spaghetti.

Fresh egg pastas include noodles such as *fettuccine*, *tagliarini*, and *pappardelle* (all ribbon-shaped in various widths), and filled pastas such as *ravioli*, *tortellini* (small, hand-pinched, ring-shaped), and *agnolotti* (small, half-moon-shaped). Popular dried pastas include spaghetti, penne (short, thick, tubular, cut diagonally), and *farfalle*

## POLENTA AND SHRIMP

- 1 cup polenta or quick-cooking cornmeal
- 1 tsp. salt
- 5 cups of water or milk (or part water, part milk)
- 2 tbsp. butter
- 2 pounds shrimp, shelled and deveined
- 1 lb sausage (kielbasa or chorizo), cut into slices
- 1 onion, sliced
- 3 slices of bacon (optional)
- 1/4 cup vegetable oil (less if bacon is used)
- 2 cloves of garlic

Seasoning: salt, pepper, and cayenne to taste

Make polenta: bring 5 cups of water or milk (or part water, part milk) to a boil in a heavy pot (best to use nonsticking surface). Lower the heat to simmer, add salt and slowly add the polenta (best sprinkled by hand) and stir with a wire whisk or wooden spoon until it forms a mush. This should take from about 7 to 15 minutes. If the cornmeal is less processed it may take a little longer. Add butter and mix it in.

Make shrimp: cut bacon into 1-inch pieces and render in large frying pan. When most of the fat has separated, add the onion and garlic and stir fry for 3–5 minutes. Add the shrimp and seasoning, and cook until it turns pink, then add the sausage and stir until sausage is warmed through.

Pour polenta into serving platter, and pour shrimp mixture on top. Serve at once.

(bowties). Some pasta types are quite specifically associated with a certain region, as is the case with *orecchiette* (little ears), a traditional pasta from Apulia (*Puglia*).

Risotto is a uniquely Italian way of cooking rice, resulting in a dish with a creamy consistency. Risotto is best made with special types of rice such as *arborio*, *canaroli*, or *vialone nano*. Popular renderings include *Milanese* (that is, with saffron—*risotto Milanese*, unlike other risottos, is traditionally served with *osso buco*, a meat dish, as a *secondo*), *con funghi* (with mushrooms), *con frutti di mare* (with seafood), and *nero* (with squid ink).

Polenta (thick cornmeal mush) is typically a northern dish. It can be soft and creamy with a sauce on top (often tomato with sausage and pork ribs), or it can be cut into shapes and baked, fried, or grilled. It is traditionally a cool-weather dish served on a wooden plate.

*Gnocchi* (dumplings) are either *di farina* (made from wheat flour) or *di patate* (made from potato). There are also *gnocchi alla romana*, made of semolina flour and traditionally served on Thursdays in Rome. *Crespelle* (crepes)

may also be a first course and can be filled with meat or with cheese and spinach.

**Sauces.** Most pasta sauces are either butter- or olive oil-based. Tomatoes are probably the next most frequent ingredient, particularly in the south. An important component of baked pastas from Emilia-Romagna is *balsamella* (béchamel sauce). Whatever the sauce (called *sugo* or *salsa*), the most important thing is just to moisten the pasta with it; Italian pasta is served with much less sauce than its American counterpart.

The best-known sauces are probably *ragù alla bolognese*, made of vegetables, tomatoes, cream, and beef and simmered for a long time, and *pesto alla genovese*, a mixture of fresh basil, garlic, pine nuts, pecorino cheese, and olive oil that is traditionally served over a mixture of *trenette* (thin strips of pasta), potatoes, and green beans.

Other popular pasta sauces are *quattro formaggi* (four cheeses); *boscaiolo* (woodsman-style), containing mushrooms, peas, ham, tomatoes, cream, or whatever the chef wants to add “from the forest”; *arrabbiata* (literally, angry), a tomato sauce with hot peppers; as well as many for seafood (which are served without cheese).

## Secondo

The *primo* is followed by a usually more austere second course of meat or fish and *contorno*, a vegetable or salad side dish.

**Meats and fish.** Meat and fish can be prepared in a variety of ways: grilled, roasted, or baked; braised with vegetables; fried, as in *fritto misto* (mixed fry); or boiled (*bollito*) and served with *salsa verde* (a piquant green sauce made with parsley) or *mostarda* (a sweet-and-sour condiment). Regional specialties include *fiorentina*, a Tuscan T-bone steak usually served rare, and *osso buco*, veal shanks in butter, garlic, anchovies, grated lemon peel, and herbs from Lombardy. *Trippla alla bolognese* is tripe with bacon, onion, garlic, and parsley, while *trippla alla romana* is tripe with tomatoes and mint. *Fegato* (liver, usually calf's liver) can be prepared *alla veneziana*, (with onions), or with sage, or grilled, or Milan-style (dipped in egg and bread crumbs and fried). Large porcini mushrooms are often treated like meat: grilled and drizzled with olive oil, garlic, and parsley as a *secondo*.

While lamb is more popular roasted or grilled, veal is prepared in many different ways. *Saltimbocca* (literally, leap into the mouth) is a dish of veal, prosciutto, and sage associated with Rome, while *scallopine alla bolognese* is veal layered with prosciutto and boiled potatoes. Thin slices of veal are often prepared in light sauces flavored with Marsala or lemon juice.

Chicken and turkey are also favored. *Pollo alla diavola* is a spicy chicken: in Abruzzi it is sautéed with hot red pepper, in Tuscany with black pepper, and in Florence with ginger. Chicken Marengo is named after a battle won by Napoleon and contains chicken, brandy,

tomatoes, olives, crayfish, and poached eggs on toast. Stuffed turkey is popular in Lombardy.

Pork is extremely popular, either as chops, roasted with fennel and rosemary as in porchetta, or made into sausages like *zampone* and *cotechino*, the former stuffed into pigs' feet.

Game, especially *cinghiale* (wild boar), *lepre* (hare), *piccioncino* (squab), venison, and pheasant, is available in season.

There is an abundance of both freshwater and salt-water fish, such as *spigola* (sea bass), *rombo* (turbot), *orata* (bream), *dentice* (dextex, a marine fish related to the porgy), and *sogliola* (sole), as well as tuna, swordfish, and *anguilla* (eel). These fish are often served grilled. *Frittura di paranza* is a dish of small fish fried in oil. Fish baked with potatoes is also a favored preparation.

*Seppie* (cuttlefish), *calamari* (squid), *polpi*, *polpettini*, and *moscardini* (types of octopus), and a variety of shellfish are also consumed. There are more shellfish in Italy than there are popular terms in English for them; for example, *scampi*, *gamberi*, *gamberetti*, *gamberoni*, *mazzancole*, and *canocchia* may be types of shrimp, prawn, or crayfish. *Cozze* and *muscoli* are mussels, and *vongole* (clams), *poveraccia* (poor or small clams), and *vongole veraci* (true or large clams) are all popular. There are many varieties of shellfish used mainly for antipasti such as *dattero* (date mussel—so called because its shell resembles the fruit), and various others called *cuore di mare* (“heart of the sea”), *tartufo di mare* (truffle of the sea), and so on.

**Contorno.** Vegetables are frequently just boiled and served at room temperature, to be drizzled with olive oil and lemon. Sometimes they are marinated in olive oil. More creative ways of cooking them include *sformato*, a creamed pudding of vegetables such as spinach or zucchini; *agrodolce*, a sweet-and-sour preparation; *in padella* (stir-fried, often with hot peppers and/or garlic); and *trifolato*, sautéed with garlic and parsley in olive oil.

*Carciofi* (artichokes) are seasonal and very popular. They can be prepared in a variety of ways; two favorites are *alla romana* (Roman style—made with garlic parsley, mint, and olive oil), and *alla giudia* (Jewish style—deep-fried whole, or cut into wedges and fried, or stuffed). Other popular stuffed vegetables are tomatoes stuffed with rice and mozzarella, zucchini stuffed with chopped meat, and eggplant stuffed with cheese or bread crumbs.

Fresh salads are usually dressed with olive oil and vinegar. *Panzanella* is bread salad made with stale bread, tomatoes, cucumbers, onion, and basil. *Caprese*, a dish of sliced tomatoes and mozzarella drizzled with olive oil and chopped basil, is available in Italian restaurants all over the world.

A classic seasonal Roman salad is *puntarelle*, shoots of a particular variety of chicory, picked while still young and tender and tossed with a dressing made with anchovies, garlic, and lemon juice. Some salads are a mix

of greens and may include *rugbetta* (also called *rucola*, *rocola*, and, as it is in English, *arugula*).

### Dolce

The next course in the Italian meal is dolce (dessert). Due to geography and climate, there are abundant varieties of fruit available most of the year, though the more interesting ones are seasonal. Many berries, figs, grapes, *nespole* (medlars—round orange-colored fruit of a tree in the rose family, which, like the persimmon, is inedible until overripe), watermelon, and Sicilian blood oranges are still seasonal. Fruits are either served in bowls of water, or cut into large chunks on a platter (watermelon), or as fruit salads; if a mixed salad, it is called *macedonia*, but salads of specific fruits, such as berries, are also possible.

The best-known Italian dessert today is *tiramisu* (literally, “pick me up”), composed of mascarpone (a very creamy, soft cheese, typically made from cow’s milk), ladyfingers, coffee, and other ingredients specific to the home or restaurant. Then there are *zabaglione*, a light fluffy whip of egg yolks and Marsala; *torta della nonna* (grandmother’s cake), made with custard and pine nuts; *panna cotta* (boiled cream), served with a variety of toppings, such as berries, chocolate, and caramel; *profiteroles* (mounds of little cream puffs filled with ice cream and drizzled with chocolate); *crem caramel*; *zuppa inglese* (literally, “English soup”), a triflelike concoction; and many different types and flavors of *gelato*. Other desserts are based on ricotta (for instance, cannoli, crisp pastry shells filled with sweetened ricotta), almonds, sponge cake (for example, *cassata*, often flavored with an alcoholic beverage such as maraschino—a wild-cherry liqueur), and chestnuts. *Monte bianco* (Mont Blanc) is a seasonal dessert of chestnut puree, brittle meringue, and whipped cream. *Crostate* are open-faced tarts filled with ricotta or jam.

Though it is technically the last course, the Italian meal does not quite end with dessert. Italians always drink their espressos after, not with, their dessert. And with or after the coffee, there are always *digestivi*—alcoholic beverages so named because they are believed to help digestion. They are made with herbs or fruit. *Amaro* (for example, *averna* and *montenegro*), *sambucca*, and *limoncello* are popular examples. The meal may also finish with almond biscotti, called *cantucci* in Tuscany, which are dipped in Vin Santo (literally, holy wine), Moscato, or Marsala—sweet dessert wines.

## TRADITION IN ITALIAN CUISINE

The reason so many people fall in love with Italy has much to do with its cuisine. Italian cooking has been influenced by diverse groups of people and places, historically and in modern times. The Americas, for instance, had a huge influence on Italian cuisine. Tomato sauce, polenta, and anything *piccante* (hot) would not exist in Italian cuisine without the introduction of tomatoes, maize (corn), and peppers—all plants native to the Americas.

The world has adopted parts of Italy’s cuisine, but not the structure of its meals. In Italy a meal is a leisurely sequence of events served in courses on separate plates, each appearing in the appropriate sequence. Americans often find it frustrating for a meal to be so lengthy, but, for Italians, dinner is often the main event and the focus of celebrations.

The cooking style is usually quite simple. There are no really elaborate sauces, and what sauces do exist are used only in small amounts, just enough to moisten pasta or delicately anoint meat or fish. Italian chefs claim, with some justification, that the secret to Italian cooking is *sapori e saperi* (flavors and skills), which implies doing little to excellent fresh ingredients.

### Similarities and Differences

While there are many differences between regions, and between households within a region, the concept of Italian food would not exist unless there were many similarities as well. There is a tendency for food experts to stress the differences instead of the similarities within the Italian food tradition. But there is much that links it as a single cuisine. Some examples are the structure of the meal, the pasta course, and potatoes used as a vegetable rather than as a staple source of carbohydrates. There is also the ubiquitous antipasto of sausages and cheeses. The types of sausage and cheese may be local—in *Remembrance of Tastes Past*, Davide Paolini estimates over sixteen hundred types—but nonetheless they are all cold cuts and cheese served on a plate before the pasta course. There are also rules common to almost all Italian cooking, such as not pairing cheese with seafood, or lemon with tomato sauce.

Having said all that, there *are* regional cuisines, and restaurants tend to be specific to a region. A restaurant serving dishes from too many regions would not be popular with Italians. There are also many foods associated with specific localities. Among the best-known examples

Many traditional Italian dishes can be traced to the Renaissance or Middle Ages. This simple preparation of prawns and clams with parsley reflects the continuity of this rich culinary tradition. Prepared at San Fruttuoso, Italy, in 2000. © OWEN FRANKEN/CORBIS.

are pizza with Naples, saffron risotto with Milan, Austrian-type dumplings with Trentino, balsamic vinegar with Modena, *fiorentina* steak with Tuscany, polenta with Venice, prosciutto and Parmesan cheese with Parma, *ragù* with Bologna, pesto with Genoa, truffles with Umbria, sheep's-milk cheese with Sardinia, and chocolate with Perugia.

### Festivals

Every Italian region has a tradition of its own with regard to Carnival, Easter, Christmas, and other holidays. Most foods prepared for them are sweet, but there are some savory dishes as well.

The best-known New Year's dish is lentils with *cotechino* or *zampone* (both pork sausages, the former stuffed into a pig's foot). The lentils represent coins and thus richness. *Croccanti* are brittle caramel and almond candies, which, molded into various shapes, decorate the center of the table at New Year's dinner. *Torta della Befana* is a fruit tart with a bean hidden inside (whoever finds the bean is crowned king or queen for the day) and is traditional for the Feast of the Magi.

For San Giuseppe Day on 19 March, *sfince* (called *zeppole* in Naples), fried dough seasoned with honey of Saracen origin, is popular in Sicily. For the feast of San Giovanni on June 24th, *tortelli* filled with greens and *ricotta* are traditional in Parma. *Amatriciana*, a pasta sauce of bacon and tomato, is traditionally served on the Sunday following *Ferragosto* (Assumption Day). *Bigne di*

*Giuseppe* (fried doughnuts) filled with cream or chocolate are eaten for Father's Day in Rome.

Carnival is a holiday full of food symbolism. Mardi Gras is literally Fat Tuesday, and the term *Carnevale* derives from Old Italian *carnelevare* (removal of meat). Both of these are major celebrations to initiate Lent, a period when people deprive themselves of some favorite food or other pleasure. *Quaresimali*, for example, are hard almond cookies prepared especially for Lent. *Pizza del giovedì grasso*, two circles of pizza with a filling of pork, cheese, eggs, and lemon, is served on the last Thursday before Lent. *Maritozzi* (raisin buns) are traditional for Lent in Rome.

On the Amalfi Coast and throughout much of the South, there is *migliaccio di polenta*, a casserole of polenta, sausage, and cheese. In Abruzzi, a Carnival dish of crepes in broth with Parmesan is consumed. Carnival is also an occasion for simple fritters: *chiacchiere* in Lombardy, *cenci* in Tuscany, and *frappe* in Rome may sound quite different, but they look and taste very similar—fried crunchy pastry strips sprinkled with powdered sugar. *Sanguinaccio* (literally, "blood pudding") is a chocolate dessert served at Carnival time around Naples.

A large variety of foods are made to celebrate Easter, from soups to main dishes to sweets, with egg as the dominant ingredient. *Pancotto*, for example, is bread soup containing butter, oil, salt, cheese, and egg, and is a traditional Easter dish in Lombardy. *Brodetto* is an egg-and-lemon soup made at Easter in Florence. An Easter

*torta* (cake) can be sweet or savory. *Torta Pasqualine*, for example, is an Easter dish from Liguria traditionally made with thirty-three sheets of very thin pastry, to symbolize each year of Christ's life. The sheets are filled with greens, artichokes, ricotta, and hard-boiled eggs.

Pizza can also be savory or sweet. *Pizza di Pasqua ternata* is a sweet Easter pizza topped with preserved fruits and nuts from the Umbrian town of Terni. *Ciambella* or *brazedela* is a ring-shaped, traditional Easter breakfast bun in Emilia-Romagna. In Naples, Easter is celebrated with *pastiera*, a type of ricotta pie. *Colomba Pasquale* (Easter dove) is a popular bird-shaped Easter cake.

Every Italian region has its own tradition with regard to Christmas sweets. Instead of fruitcake, there are a variety of fruit breads. In Liguria there is *pandolce*, made with candied fruits, nuts, and flavorings. In Tuscany there is *panforte*, also called *panforte di Siena*, a hard, flat concoction popular since the thirteenth century. This characteristic sweet, made of toasted nuts stirred into hot honey caramel, has many virtues, including the fact that it can be stored for long periods of time.

Since the 1950s, *panettone* (literally, "Tony's bread") has become popular all over Italy at Christmas time. The custom of consuming *panettone*, especially during the year-end holiday season, spread from Milan throughout Italy. There are variations, however. *Pampepato* is a Christmas cake from Ferrara made with pepper, chocolate, spices, and almonds. In Rome the Christmas cake is *pan giallo*, a fruit-and-nut cake, originally made with saffron, thus its name, which literally means yellow bread.

In Naples women prepare for the arrival of Christmas with delicacies made of *pasta di mandorla* (marzipan) and with *struffoli*, tiny pieces of soft pastry formed into balls, fried, coated with honey, and sprinkled with bright and colorful candied sugar and pieces of candied fruit peel. Sicily has *cuccidatu* or *bruccellato*, a ring-shaped cake stuffed with dried figs, raisins, and nuts, and spiced with cloves and cinnamon.

Christmas also provides its share of savory specialties. In many homes, fish is the preferred main course for Christmas Eve dinner. In Lombardy, stuffed turkey and *tortelli* (similar to ravioli) filled with squash and crushed amaretto cookies are traditional for Christmas, while in Bologna tortellini (small, hand-pinched, filled ring-shaped pasta) is traditional for Christmas Day.

*Papassine* is a traditional Sardinian sweet for all occasions—Easter, Christmas, and All Saints' Day, for example—made with dried fruit, lard, orange, and eggs.

**JAMS, JELLIES, AND PRESERVES.** An atmosphere evoking both enchantment and delight surrounds the consumption of jams, jellies, and preserves. Children and adults alike enjoy sweet quince paste from Spain, orange marmalade from Scotland, candied fruit from France, or ginger in heavy syrup, an English specialty. No doubt they would be surprised if told that there is not the least gastronomical ambition to be found in the origin of these delicacies—only the need to preserve fruit and other plants. They would be even more surprised to find out that the earliest confectioners were apothecaries, and the first preserves nothing but medicines. Sick people were very lucky in those days: they were permitted to eat sweetmeats to their hearts' content.

### Preserving Food

Since prehistoric times, people have been very concerned about starvation, so they have protected themselves against hard times by storing the products of their crops and harvests. Various preserving methods were elaborated over the course of centuries; the earliest ones consisted in storing fruits far away from air and light, desiccating them, or preserving them in an antiseptic bath.

In the first century C.E., the Roman agronomist Columella described these techniques in his work *De re rustica*. According to Columella, the ideal means to preserve pears or peaches consisted of putting them in small wooden boxes, which were to be carefully closed so that air could not get in. As for figs and grapes, they were to be dried in the sunshine. Finally, Columella suggested the use of a preservative to retard decomposition, called *conditio* (from Latin *condire*, 'to condite, or preserve'. This use of *conditiones* to preserve food was called *conditus* (or *conditum*). There are various types of *conditiones*—salt, vinegar, sweeteners—that have preservative properties and do not exclude each other; in other words, their effects are cumulative.

**Fruit pickled in vinegar and salt.** Apicius, a Roman gastronome who lived in the time of Columella, preserved peaches in a mixture of salt, brine, and vinegar. Pickled fruit and vegetables are the modern version. But by its very nature, fruit needs sweet *conditiones*, which emphasize its flavor and heighten its fragrance. Since they did not know of the existence of sugar (see below), the ancients suggested several alternatives.

**Fruit preserved in sweet wine.** One alternative was *passum*, a high-alcohol, very mild wine made of raisins and used by Columella for pears and plums. The fruit was picked a short time before becoming ripe and was placed in a terracotta receptacle coated with pitch. It was then covered with *passum* so as to be soaked in liquor. A plaster-coated lid was placed on top. These *conditi in passum* can be seen as the forerunners of today's fruit in liquor.

**Fruit preserved in wine syrup.** Also used was *sapa* or *defrutum*, grape must that has been cooked and reduced by two-thirds or one-third, respectively. Columella used it for apples, pears, and sorbs. To make sure they were submerged in the syrup, a handful of dried fennel was placed on top. The lid was carefully coated with plaster and pitch so that air could not get in. This fruit bath of thick sugary grape juice is the forerunner of fruit preserved in syrup, which is now sterilized in order to protect it against decomposition.

**Fruit preserved in sweet-sour pickle.** Columella also concocted a sweet-sour *conditio* with vinegar and either *sapa* or *defrutum* for sorbs, plums, sloes, pears, and apples picked before they were fully ripe. They were then dried for one day in the shade. A mixture consisting of equal parts vinegar and *sapa* or *defrutum* was poured on the fruit. Columella recommended adding a bit of salt to prevent infestation by small worms or other animals. Finally, he made it clear that the fruit could be preserved even longer by adding two-thirds of *sapa* and one-third of vinegar. Our cherries in vinegar, which are served with stews and pâtés, are based on the same principle: they are covered with a bath consisting of a sweet element (two-fifths of sugar) and vinegar (three-fifths). We should not be surprised at the use of salt in the Roman recipe. It is a flavor enhancer, provided it is used in small quantities.

Apicius suggested another sweet-sour *conditio* based on *sapa* and blackberry juice. It was poured on blackberries placed in a glass vessel. The author specified that they could be preserved for a long time in this manner.

**Melomeli and Marmalade.** And—last but not least—there is honey. Its preserving properties have been recognized for a very long time. The corpse of Alexander the Great is said to have been kept in honey. Columella

therefore claimed that honey stopped putrefaction and protected a corpse from decomposition for several years. Columella was, however, reluctant to use it for his fruit *conditi*, as he believed that fruit preserved in honey lost its flavor. J. André, in *L'alimentation et la cuisine à Rome*, suggests that his reluctance might be due to the fact that the production of honey was rather limited in those days.

Nevertheless, Apicius used honey as a *conditio* for figs, apples, plums, pears, and cherries: "Gather them carefully with their stalks and put them in honey so that they do not touch each other." Apicius paid particular attention to quinces, which he preserved in a mixture of honey and *defrutum*: "Choose faultless quinces with their twigs and leaves, and put them in a receptacle, and pour over honey and *defrutum*; you will keep them for a long time." In fact, Columella also made an exception for quinces, and he likewise recommended preserving them in honey. According to Columella, quinces should be picked when the sky is clear and the moon on the wane; they should be wiped and put into a new receptacle filled up to the rim with excellent very liquid honey, so that each fruit is covered. Not only does this method preserve fruit, but it also yields a drink called *melomeli* (from Greek *melon*, 'quince' and *meli*, 'honey'), administered to sick people when they run a fever.

The Greek physician Dioscorides, who was Columella's contemporary, gave a slightly different recipe in his herbarium entitled *De materia medica*. *Melomeli*, which he called *cydonomeli* (from Cydonia in Crete, where the best quinces were produced), appears in the chapter about wines: "First of all, quinces should be deseeded, then entirely covered with honey, which becomes good after one year and tastes like *oenomeli* (honeyed wine)." So, according to Dioscorides, quinces are to be deseeded first—in other words, opened and not left whole—unlike Columella's recipe.

Additionally, Dioscorides gave two recipes for *cydonites oenos*, "quince wine." In the first one, quinces are to be cut in pieces like turnips and then deseeded. For twelve pounds of fruit, forty liters of must are needed to cover them. The mixture should macerate for thirty days until the wine gets clearer. In the second recipe, quinces are crushed and the juice is squeezed out. The proportion is five liters of juice to one pint of honey, and the whole is then mixed up.

*Melomeli* and *cydonites oenos* have the same therapeutic properties: they are astringent, facilitate digestion, relieve dysentery, and are good for people with liver, kidney, or urinary ailments—a real cure-all, if you add the antipyretic qualities ascribed by Columella to his *melomeli*.

According to modern-day experimentation with these ancient recipes, both *melomeli* and *cydonites oenos* are slightly fermented drinks tasting like mead, with a very fruity and particularly original flavor. Dioscorides was actually right when he compared them to honeyed wine.

It is rather surprising to note that *melomeli* (also spelled *malomellus* in the seventh century), which is not a jam, is the origin of the word "marmalade," derived from it via Spanish *membrillo* and Portuguese *marmelo*, both meaning 'a quince'. Indeed, before it became, from the seventeenth century onward, "a jellied conserve of Sevilla oranges (with such alternatives as lime, grapefruit, lemon, or ginger), marmalade was a preserve confected from quinces boiled with honey or sugar" (Wilson, 1985, p. 15). The ancients did not know marmalades made of citrus fruit (they were introduced by the Arabs in the Middle Ages—see below), but they created jelly, jam, and quince paste.

### Quince Paste

In the second century C.E., the Greek physician Galen wrote that the Romans were importing quince paste (*meloplacounta*, derived from *melon*, 'a quince', and *plakounta*, 'a tablet') from the Iberian Peninsula: "It is firm and hard, and has been brought to Rome in very large quantities. It consists of honey and crushed quinces cooked in honey." It is not only a delicacy, but also a medicine aimed at strengthening a debilitated stomach, as the distinguished physician put it.

So, according to Galen, quince paste originated in Spain. It has remained up to now a specialty of the Iberian Peninsula (*pasta de membrillo* in Spain and *marmelada* in Portugal). Unfortunately, Galen does not give the recipe for this confection. It is, however, to be found in a late text of Byzantine origin attributed to the last representative of Greek medicine, Paul of Aegina (seventh century): "Six pounds of quinces are cooked in wine until they have softened up. Then they are crushed. Eight pounds of honey are added and the whole is cooked slowly until the mass doesn't leave the slightest trace on the hand. Various drugs are added to the paste, which is eventually divided into half-ounce tablets."

### Quince Jelly

Galen also gives the recipe for a drug based on quince juice that he claims to have invented and is particularly appropriate for stomach ailments. This drug survived for centuries under the name of *diamelon* or *cydonitum*. Its preparation involves mixing two parts quince juice, two parts honey, and one part vinegar. Ginger and pepper are optional. The mixture is cooked until it has thickened to the consistency of honey (*melistos pachos*). Modern-day experimentation with this ancient recipe has yielded a beautiful translucent red jelly with a pleasing peppery flavor.

### Quince Jam

In the fourth century C.E., the Roman agronomist Palladius revived Galen's quince jelly, which he called *cydonitum*. He added a second formula: "You first peel ripe quinces, you cut them into small pieces, excluding the hard parts you may find inside. You then boil them in honey, until the mixture has been reduced by half, and you sprinkle it with fine pepper while they are cooking."

If the ancients did indeed know about pectic fermentation (pectin makes the process of jelling possible), they did not make the most of it. In fact, they only applied it to quinces, which are actually rich in pectin; when they are cooked with an acid (like vinegar in *diamelon*), jelling takes place almost automatically. C. Anne Wilson, in *The Book of Marmalade*, explains that the ancients preferred fruit “in their fresh, uncooked state to fruit preserved in wine, syrup, vinegar, or honey.” Quinces were an exception, because, if not totally ripe, they remained hard even in honey. It was to avoid that risk that quinces were precooked. This led to the discovery of pectic fermentation. “The high pectic content of some other sharp fruits may never have been discovered because there was no incentive to precook them in honey. So quinces remained unchallenged in the field of the pectin-jellied conserve.”

### Another Fruit Jam

There is another jam in Greco-Roman medieval literature: *diaoporon* or *medicamentum ex pomis*, which is at the same time an antidiarrheic and good for digestion. Various fruits (apples, pears, pomegranates, and especially quinces) are cooked in honey, *sapa*, and must (the pulp and skins of grapes)—“*donec omnia quae indita sunt liquata in unitatem quadam coeant*”—until all ingredients have been reduced to a uniform mass, according to Celsius, a Roman physician of the first century C.E. As for Columella, he indicated that *diaoporon* must be cooked—“*donec crasamen in modum fecis existat*”—until it has reached the consistency of feces. This is in fact what it looks like when it has been cooked in that manner. Its flavor, however, is not unpleasant, as Celsius experienced (“*id gustu non insuarve est*”). This is a rather surprising comment for Celsius, since he wrote at the beginning of his treatise, *De Medicina*, that “all *condita* are unserviceable for two reasons, because more is taken owing to their sweetness, and even what is moderate is still digested with some difficulty.”

### Fruit and Honey Syrups

The ancients also knew of other fruit and honey preserves. Criton, a Greek physician who lived at the beginning of the first century C.E., created *diaroion*, the forerunner of grenadine. It is made of pomegranate juice, cooked until it has reached the consistency of lime (*gloiou pachos*), honey, and, optionally, drugs such as myrrh. *Diaroion* is particularly appropriate in the treatment of mouth ailments.

Then, there is the blackberry-based *diamoron*, a famous remedy created by Heras (a contemporary of Criton), which is still mentioned in modern pharmacopoeias. It is prepared in the same way as *diaroion* and has the same therapeutic effects. It has also been found to be effective in treating gum inflammation.

### Nougat and Marzipan

The ancients paved the way for honey and dried-fruit preserves with almonds as the main ingredient. This mix-

ture eventually gave birth to marzipan and nougat, and the Arabs (see below) developed the manufacturing technique.

At the end of the fifth century B.C.E., the *Hippocratic Corpus*—in fact, just a few parts were written by Hippocrates himself—gives an interesting formula to cure pleurisy. The ingredients are honey (with an emollient effect on the throat), scilla (a bulbous herb useful as an expectorant), and almonds (with well-known cough-suppressing properties). The recipe is as follows: “Cut scilla bulbs into slices and cook them in water; when they have boiled, tip the water; pour water again and cook the scilla again until it looks mushy and well cooked; crush it in equal pieces, add roasted cumin, white sesame, fresh almonds; crush all these substances in honey.” This may be the forerunner of marzipan.

As for Galen, he suggested a cough mixture made of sweet almonds and honey with other dried fruit such as pine kernels (which also have cough-suppressing properties), grilled flaxseeds, flag, and tragacanth gum (which have the same therapeutic effects). A modern version is to cook the mixture and let it cool down under a weight. The result is a delicious candy tasting like the famous black nougat from Provence served at Christmastime.

### The Arab Contribution

It was not until Arab times (in the times of the Caliphate of Baghdad, more particularly the Abbasid dynasty) that there was some progress in the sciences. It should be noted, however, that much of the confectionery technology attributed to the Arabs was in fact developed in Sassanian Persia and known to the Byzantine Greeks. Further, sugar was not much used in the Near East until a system of irrigation could be developed and a source of wood could be found for processing it.

First, the Arabs introduced sugar in medicines and in cooking. Sugar diluted in water yielded a new confection called *sharab* in Arab and *syrupus* in Latin. Sugar syrup was used to manufacture various preserves and sweetmeats, more particularly *sharab al-fawaki* (*syrupus de fructibus*), an updated version of *diaroion* and *diamoron* in which Arabs replaced honey with sugar and used various comfits and sweetmeats such as fudge, tatty, and marshmallow.

Moreover, the Arabs went deeper into the subject of pectic fermentation. They created the first marmalades of citrus fruit; most of them, however, were candied in honey, not in sugar: an example is the lemon marmalade of Avicenna (980–1037). (Islamic traditions often use honey over any other form of sugar although they were one of the first to have sugar.)

In Spain, the Arabs developed the traditional fruit pastes (see above) by creating new varieties with roses, violets, orange peels, kernels, and green walnuts (well known in Byzantine Armenia). They were also made with

honey. As for the traditional quince paste, it was sugar-candied from the thirteenth century onward.

Finally, the Arabs developed dried-fruit pastas and created various kinds of marzipan and nougat—sometimes with honey, sometimes with sugar.

**Pseudo-Mesue: the father of European confectionery.** Pseudo-Mesue, a twelfth-century physician probably of Italian origin, was the person who introduced Arab confections into Christian countries. He also invented new ones. He wrote jam recipes (apple, plum, peach) that were revolutionary for his time because they were made with sugar, not with honey.

It was not until the late Middle Ages that confectionery developed into what it is now. New recipe books evidencing this evolution were published. *The Libre de totes manieres de confits*, drawn up in the fifteenth century and written in Catalan, had many imitators during the Renaissance. They include: *De secreti* by Alexis of Piedmont (Venice, 1555), the preserves-maker of the French physician and astrologer Nostradamus (Lyons, 1555), and *The Treasure of Commodious Conceits and Hidden Secrets* by John Partridge (1573).

## JAPAN.

*This entry includes two subentries:*

Traditional Japanese Cuisine

Contemporary Issues in Japanese Cuisine

### TRADITIONAL JAPANESE CUISINE

The Japanese eat three meals a day, and afternoon and late-night snacking is normal. This popular expectation of three meals a day dates to the middle of the Edo period (1600–1868) (Tsuji and Ishige, 1983, p. 306). One traditional definition of a meal in Japan is that it includes rice, soup, pickles, and at least one side dish. In normal home cooking these components are usually served together rather than as separate courses. In specialty restaurants, the main course is sometimes served first accompanied by sake (rice wine), followed by rice, soup, and pickles to mark the end of the meal.

#### Rice

Rice has been cultivated in Japan in wet paddies for about two thousand years. Introduced from southern China, the preference in Japan has always been for a glutinous, short-grained variety. Traditionally rice is boiled or steamed, and in modern kitchens it is usually prepared in automatic rice cookers.

The words for cooked rice in modern Japanese, *meshi* and *gohan*, are also used to mean a "meal." The degree to which rice has been the central staple of Japanese food is debated (Ohnuki-Tierney, 1993, pp. 30–43), and historically rice has been supplemented by other carbohydrates, such as millet and sweet potatoes. Nonetheless rice is idealized as the core of any Japanese meal. If noodles constitute the main starch of a meal, rice is not served, but such a meal is also considered more of a snack than a proper meal. Gretchen Mittwer points out that the midday noodle snack became popular in early historic periods, when only two meals per day were eaten (Mittwer, 1989, p. 23).

Rice, sake, and the pounded-rice paste called *mochi* are powerful symbols in Japan. Rice and its products symbolize the relation of Japanese people to their deities, the nature of community in Japan, and Japan's history and aesthetics, and in the end rice is a symbol of the Japanese self (Ohnuki-Tierney, 1993, pp. 8–11, 127–131).

#### Soups

Three major ingredients, which may be used together or separately, create the basic stock of a Japanese soup (*dashi*). The first is *katsuo-bushi*, or dried bonito. The bonito is dried and processed to create hard, woodlike pieces that are easily stored. A planelike tool is used to take shavings from it that are dropped into hot water, then strained out. Instant powders are often substituted. The second major ingredient is kelp (*konbu*), which is also available as an instant powder. *Konbu* and *katsuo-bushi* often are used together to create a stock. The third ingre-

dient, shiitake mushrooms, are boiled with or without kelp to create a vegetarian soup stock used, for example, in *shojin-ryōri*, the vegetarian cuisine of Buddhist temples (Ishige, 2000, p. 1178).

Two main types of soups are based on these stocks. Clear soups (*suimono*) are considered light and elegant and are served in lacquered bowls with lids. A bit of salt and soy sauce is added to the broth along with two or three small bits of solid food, perhaps a piece of fish, a sliver of vegetable, and an aromatic garnish. When the lid is lifted, the delicate fragrance escapes, and the aesthetic arrangement of the solid foods within the bowl is an added enjoyment (Tsuji, 1980, p. 151).

Miso soups comprise the second major class of soups. Miso is a paste made from soybeans and barley inoculated with a fungal culture and allowed to cure for a year or more. A great variety of misos exist, some smooth, others chunky. They range in color from light beige (called “white”) to medium red or brown to nearly black. Some are sweet, while others are quite salty. Because this is a bean-based ingredient, miso soups are a rich source of protein.

To make a miso soup, a variety of miso is selected and dissolved in hot stock. The cook adds seasonal vegetables, such as parboiled fiddlehead ferns or eggplant, and perhaps a few cubes of tofu (white, mild-tasting curds made from soy milk). Miso soup is more common than the clear soups, and more filling as well.

## Pickles

Japanese pickles (*tsukemono*) are primarily pickled vegetables. They exist in great variety and add texture and diversity to even a simple menu. Originally pickling preserved vegetables for use through the winter, but pickles have come to occupy a place in the menu year-round.

Daikon radishes, Chinese cabbages, cucumbers, eggplants, and turnips are often pickled. Rubbing the vegetable in salt, then placing a weight on top to force out liquids is a common method, as is packing the vegetables in miso, sake, sake lees, or rice bran. The use of vinegar is a relatively less-important pickling method in Japan (Yoneda, 1982, pp. 89–92).

Green, unripened Japanese plums (*ume*) are the only fruit regularly pickled, and they are prepared with salt and red perilla leaves (*shiso*). The resulting pickle, called *umeboshi*, is salty, sour, and red. It is considered an appetite stimulant, consequently it is often served with breakfast (Richie, 1985, p. 85). *Umeboshi* is commonly used to flavor *onigiri*, a favorite picnic food, which is a ball of rice with something inside.

Traditionally pickles were made at home, and many regional specialties developed. However, most consumers buy pickles in supermarkets or department stores. There open vats of decoratively arranged pickles are displayed, and the attractively pungent smells are obvious immedi-

ately upon entering the store. Pickles are also frequently sold as regional souvenirs.

## Side Dishes

Side dishes, *okazu*, add savor to the rice that is traditionally understood as the central portion of the meal. Non-Japanese people are tempted to call some of these the entrée of the meal, as the side dishes might include grilled fish or deep-fried pork (*tonkatsu*), but this is at odds with the traditional understanding. Side dishes could also include sweet vinegared cucumbers, steamed enoki mushrooms, or *hijiki* seaweed stewed with carrots. A simple meal might have only one side dish, but elaborate meals would have many. Some major *okazu* include salads, tofu, seafood, and meat.

**Salads.** Traditional salads are served cold and can be divided into two basic categories, vinegared salads (*sunomono*) and salads with heavier dressings (*aemono*). The vinegar-based dressings usually include a basic soup stock (*dashi*) and soy sauce and might also include some fruit juice, ginger, or grated daikon radish as well. Heavier dressings are often made with pureed tofu, ground sesame seeds, or miso.

Like the soups, which call for seasonally available fillings, salads highlight seasonal materials, including fruits, vegetables, and fish or shellfish. Depending on the materials, some might be steamed, parboiled, or grilled in preparation, but they are always cooled and dried before the salad is assembled. Typical salads might include crab with thinly sliced cucumbers in a vinegar and ginger

Seaweed has been an ingredient in traditional Japanese cookery for many centuries. It is a rich source of iodine and trace elements. Shown here is kelp. COURTESY OF FIELD MARK PUBLICATIONS.

dressing or parboiled spinach dressed with ground sesame seeds, soy sauce, dashi, and a bit of sugar (Tsuji, 1980, pp. 241–242, 247, 253).

**Tofu.** Mentioned above as a common ingredient for miso soup and as a base for thick dressings, tofu has attained worldwide recognition. It was originally brought to Japan from China, perhaps in the 900s by the delegations of Buddhist priests who studied there. As priests were allowed to eat neither meat nor fish, this high protein food was doubtless appreciated. By the 1100s tofu was widely used in Japan.

To make tofu, soybeans are cooked, then strained. The resulting liquid is soy milk. A coagulating agent is added to the soy milk, and the resulting curds are shaped into blocks. Tofu is an inexpensive ingredient that lends itself to many styles of preparation. In the 1780s two best-selling books each promised one hundred tofu recipes (Richie, 1985, pp. 34–41).

Two simple ways of serving tofu are popular. *Hiyayakko* is chilled tofu cut into bite-sized pieces and served with a dipping sauce of soy sauce and grated ginger or chopped scallions. *Yudofu* is tofu cut into cubes and heated in hot water seasoned with kelp. Once warm, the cubes are lifted out and dipped in a heated sauce flavored with grated daikon radish.

*Iridofu* is made by stirring tofu over heat with bits of carrots, shiitake mushrooms, and snow peas. *Dengaku* is tofu roasted on bamboo skewers, then spread with flavored miso and roasted again.

Tofu can be deep-fried. Cut into thick slices and dredged in potato starch, it is fried to make *agedashi-dofu* and is served with a sweetened soy sauce dip. Cut into thin slices and double-fried, *usuage* is often sliced in thin strips and used in boiled dishes because it holds together well, or it is used as a small edible pouch for sweet vinegared rice to make *inari-zushi*.

In addition to the raw and fried versions, tofu is freeze-dried. This product is easily stored, and when re-constituted with water, it has a distinctive spongelike texture. It is often simmered with vegetables or put into soups. Known commonly as *koori-dofu* and *shimi-dofu*, this tofu is also called *kooya-dofu* or Kooya tofu. It is said that monks on cold Mount Kooya discovered their tofu was frozen. When in their thriftiness they used it anyway, they were pleasantly surprised.

**Seafood.** Japan is surrounded by the sea. Both cold and warm currents lap the islands, creating a variety of ecological niches. This in turn supplies Japan with a variety of fish, shellfish, and marine vegetables. The general attitude in Japan is that the freshest fish are best enjoyed raw. Fish that are not as fresh should be grilled with salt, and fish of even lesser freshness should be stewed with soy sauce or miso (Ishige, 2000, p. 1177).

Since the Edo period raw fish has been served as sashimi, sliced into bite-sized pieces and garnished. Grated daikon radish or wasabi, a Japanese root product related to horseradish that adds pungent flavor, is provided along with a small side bowl of dipping sauce. The radish or wasabi condiment is added to the dipping sauce to taste, then the fish slices are dipped and eaten. In casual home cooking this dipping sauce might simply be soy sauce, but in restaurants it is often soy sauce reduced with sake (Tsuji, 1980, pp. 159–160). Before the Edo period raw fish was usually served as *namasu*, in which it is sliced and marinated in flavored rice vinegar, but with the advent of commercial-scale soy sauce production, the shift was to sashimi (Ishige, 2000, p. 1177).

Also in the Edo period sushi arose, originally a means of preserving fish. The fish was salted, then packed in cooked rice. With lactic acid fermentation, the rice developed a vinegarlike taste and preserved the fish, but the rice was discarded when the fish was served. By the 1400s people began to eat the rice as well, and in the Edo period slices of fresh fish were served atop small mounds of vinegared rice, often with a dab of wasabi added to the top of the rice (Ishige, 2000, p. 1177). This came to be known internationally as sushi, but more properly this style that developed in Edo (now Tokyo) in the early 1800s is *nigiri-zushi*. The older tradition of western Japan, particularly of Osaka, was to pack vinegared rice into a mold, cover the rice with marinated fish, remove the contents from the mold, then slice the resulting loaf into bite-sized pieces (Richie, 1985, p. 15; Tsuji, 1980, p. 288).

A great many vegetables are harvested from the seas. Kelp was mentioned above for its importance in making soup stock. *Wakame* is often used as a solid ingredient in soup and might be mixed with a variety of seaweeds in vinegared salads. Agar-agar (*kanten*) is important in traditional confections. Nori is well known as the nearly black paperlike sheets that wrap certain types of sushi (Tsuji, 1980, pp. 54–55, 72–73, 79–80, 97).

**Meat.** Eating meat was long a taboo in Japan. An imperial decree against eating several kinds of meats was issued in 675 C.E. In the Heian period (ninth to twelfth centuries), with the increased importance of Buddhism, meat eating largely disappeared in cities, though professional hunters were still active in remote areas. Nevertheless animals were not raised for slaughter. Cattle existed only for pulling carts and plows, and even their milk was not used. Buddhist priests were further enjoined from eating fish also, but the general populace ignored this stricture (Ishige, 2000, p. 1176).

Following Ishige's assertion that "traditional cuisine" is that of the Edo period, beef, popularized in the Meiji period (1868–1912), might be outside the focus of this article (Ishige, 2000, p. 1181). The innovations of the Meiji period succeeded, however, because they adapted to the norms of traditional cuisine (Cwiertka, 1999, p. 54), and the smooth shift eventually came to be seen as continuity.

With the opening of Japan to the West in the 1850s, the country quickly began to incorporate aspects of Western life, often with a catch-up mentality. In the 1860s the first slaughterhouse for cattle was built, and by the early 1870s beef eating was a fad. In 1873 the emperor endorsed the new custom. This gave rise to the dish called *sukiyaki*, in which beef is simmered in a traditional broth of sweetened soy sauce and sake along with other traditional items, such as grilled tofu, shiitake mushrooms, and chrysanthemum greens (*shungiku*) (Richie, 1985, pp. 21–25). The popularization of pork seems to have followed in the 1930s in the form of *tonkatsu*, a deep-fried, breaded pork cutlet (Richie, 1985, pp. 49–51).

This popular acceptance of distinctly foreign foods is paralleled in Japanese history by tempura, the crisply coated, deep-fried fish and vegetables known around the world. The Portuguese were a presence in Japan in the second half of the sixteenth century, and they apparently batter-fried their fish. The method spread, and by the mid-1700s tempura was popular, sold mainly from street carts (Ishige, 2000, p. 1177).

## Beverages

The two most representative beverages of Japan are tea and sake. Tea was first imported into Japan in the 800s from China. The tea was formed into bricks, then allowed to cure by fermentation. These blocks of tea were powdered and boiled. After some popularity among the aristocracy, tea drinking in Japan died out. It was reintroduced in the 1200s, this time as powdered green tea. This is the tea of the famed tea ceremony of Japan, but its popularity was limited, perhaps due to the complex rituals associated with the drink. Sometime in the 1600s tea was reintroduced to Japan, this time as an infusion made with the green leaf. This style of tea has become dominant in Japan and is served in homes, offices, and restaurants. In the Meiji period black, Western-style tea

was introduced, and by the 1920s it was widely popular (Ishige, 2000, pp. 1180, 1182; Kumakura, 1999, p. 40).

Sake, like rice and *mochi*, carries symbolic importance. It is offered to Shinto deities both at home altars and at large public shrines, and it is the drink that seals the marriage in any Shinto wedding ceremony. Although sake has a long history, modern sake is clear and has a higher alcohol content (15 to 17 percent) than before the twentieth century. Steamed white rice is inoculated with a mold called *kofi* (*Aspergillum oryzae*), which starts the fermentation. About two days later, sake yeast (*Saccharomyces cerevisiae*) is added. Including refining, sake is produced in forty-five to sixty days. Sake does not improve with age; it should be consumed soon after production. Special cups and serving bottles are used for sake, and a fairly elaborate serving etiquette accompanies pouring drinks. While beer and whiskey are more popular than sake, the serving etiquette of these two drinks is based on that of sake (Tsuiji, 1980, pp. 336–340).

## Seasonality

The Japanese often pride themselves on the seasonality of their traditional food. In the mass market many foods are available without regard to season, but most traditional Japanese meals include seasonal aspects. As noted above, the solid ingredients in soups and the selection of materials for salads both announce the season in everyday meals.

Certain foods are only harvested and sold seasonally. The puffer or blowfish (*fugu*), which can quickly kill the eater if the poisonous liver is not properly removed, is available only in cold months, when the poison is said to be less potent (Richie, 1985, pp. 47–48). A fragrant and expensive mushroom, *matsutake*, is only found in the fall. The *ayu*, a fresh-water fish rather like a trout, is a food for early summer.

Some special days are marked by serving particular dishes. On 7 January it is traditional to eat a rice porridge made with seven springtime herbs (*nanakusa-gayu*). In August, on the day of the ox as calculated by a traditional ephemeris, people eat grilled eel (or more innovatively some form of beef) to strengthen themselves to withstand the remaining days of summer. On the first day of winter many homes serve *tooji kabocha*, pumpkin cooked with sweet *azuki* beans.

Other foods are served differently in different seasons. Some prefer *soba* noodles served cold with a small cup of cold dipping sauce on the side, but the same noodles are more often served in a bowl of hot broth in the winter. Early in the Edo period sake was warmed only in fall and winter (Ishige, 2000, p. 1180). Since then it has often been served warm throughout the year, but after the 1990s cold sake experienced a resurgence, especially in the summer. Miso soup as served in the cuisine of the tea ceremony is a blend of red miso with white. In the depths of winter the mixture is almost completely red

## BENTO BOX

Japanese *bento*, or *obento*, is a meal compartmentalized in a lidded box, usually made of lacquered wood. Often square or rectangular in shape, there are also round and oval types in which cut bamboo leaves are used to separate each food item. A *bento* box typically contains rice, pickles, braised vegetables, and a protein such as fish, poultry, or meat, each placed in individual sections. The new, internationally popular *bento* box lunch, served in a humble wooden or plastic box and usually offered by Japanese restaurants, is directly related to the *makunouchi* (meaning "between curtains") *bento* developed during the Edo period (1600–1868). This type of box lunch was intended as a conventional meal to be eaten during intermission at kabuki plays. During the same period, a more stylish type of *bento* box, called *shokado bento*, evolved in Osaka. In this type, each food item is placed in a small individual porcelain or lacquered wood dish, and then in a larger lacquered square or rectangular box. *Shokado bento* are not meant to be used as portable lunch boxes. Displaying colorful food rather artfully (much like traditional *kaiseki*, the elegant multi-course meals served prior to formal tea ceremonies), the *shokado bento* can be ordered in restaurants and other formal settings.

During the Meiji (1868–1912) and Taisho (1912–1926) periods, and with the arrival of railway stations, the *eki-ben* (meaning "station meal") box evolved. These boxes, although made of plastic or other lightweight material, are still available, often offering regional

foods related to the station where people board the train. *Eki-ben* is, perhaps, also related to the original lunch-on-the-go given to the soldiers of the Heian period (794–1192). Once called *tonjiki* (meaning "soldier's meal"), *onigiri* is a handful of rice with salty fish or pickles set in the center and wrapped triangularly with *nori* (dried laver sheet), a common red algae.

Consistent with the Japanese appreciation for specificity, there are various types of *bento* box meals related to the particular individual or event. For example, a mother might prepare *tsugaku bento* for her child's school lunch or *aisai* (meaning "beloved wife") *bento* for her husband to take to work. *Koraku bento* are prepared for outdoor activities (for example, hiking), *domu bento* are sold at baseball stadiums, and *hokaben bento* are take-out meals.

miso, which is considered hearty and warming. Into spring more white miso is blended in, and by summer it is almost completely white miso, which is considered a much lighter dish.

The dishes and plates on which food is served are also seasonally appropriate. The deep, warm-looking bowls of winter gradually give way to the flatter, more airy and open-looking bowls of summer. Glass, because it reminds one of ice, is used to give a cool look to a set of summer dishes. Dishes might also have painted decorations appropriate to the seasons, such as cherry blossoms for spring or colored leaves for fall.

**Seasonal sweets.** Seasonality is also marked in Japan by serving sweets associated with particular seasons or holidays. The doll festival is a minor holiday on 3 March. Families with girls display elaborate sets of decorative dolls that represent the imperial court of the Heian period. Girls might have parties at their homes and serve

two traditional foods, *bishi-mochi*, diamond-shaped multicolored sweets made with puffed rice, and *amazake*, an unclarified, milky-white sake sweetened and flavored with ginger. *Arare* and *amazake* are sold in department stores and local convenience stores ahead of the festival date and are often shared as snacks (*o-sanji* or *o-yatsu*) for afternoon breaks in offices and other workplaces. While people with daughters to celebrate on this day have an obvious reason to buy and serve these sweets, many others do so as well. These two dishes are recognized as seasonal foods and are available once a year.

Other minor holidays are associated with particular sweets, such as the vernal and autumnal equinoxes, boys' day (5 May), and the celebration of the full moon of fall. The cherry blossom season also has its own associated sweets.

**The New Year.** Of all the holidays in Japan, New Year's is by far the most elaborate. It is celebrated on 1 Janu-

Contemporary variation on a traditional bento box as served at a Japanese restaurant in New York City, 2002. PHOTO CORINNE TRANG.

ary of the Western calendar, and most stores and offices are closed until 3 January. Special trains run all night shuttling people to major Shinto shrines, where they pray for a good year. Children receive envelopes containing money from their parents, relatives, and family friends, and large bundles of postcards with New Year's greetings are delivered on New Year's Day.

Through December many workplaces and university clubs hold year-end parties. These are often elaborate feasts of traditional Japanese food washed down with copious amounts of beer, whiskey, and sake. These parties are called *boonen-kai*, literally a gathering for "forgetting the year," specifically burying grudges of the past. Some groups host more abstemious Christmas parties instead, at which the food is usually Western and the drinks include sparkling wine.

In the last few days of the year, a New Year's delicacy called *mochi* was made traditionally. Glutinous rice was steamed, then put in a large mortar standing about two and a half feet tall and two to three feet in diameter. One person would swing a large mallet, pounding the mass of rice, while a second person reached in and turned

the rice between each stroke. The resulting dough was cut into small balls or rolled into a large sheet and later cut into squares. Today, most people buy processed *mochi*.

It is traditional that no (substantial) cooking takes place for the first three days of the new year, so elaborate side dishes are prepared at the end of the year and beautifully arranged in decorative lacquered boxes for the New Year feast. While many housewives preserve this tradition, others order these traditional dishes ahead of time from caterers.

On the last night of the year, it is traditional to eat buckwheat noodles, *soba*, called *toshi-koshi soba* (crossing-the-years *soba*). The noodles are served in a hot broth, typically garnished with scallions, fish sausage (*kamaboko*), or perhaps a piece of batter-fried shrimp (*tempura*). These long and thin noodles are eaten in the hope that life may be long and thin (virtuously upright).

On the morning of 1 January the family eats the most ritually elaborate meal of the year together. The foods prepared for this meal are called *o-sechi ryoori*. Many are good luck foods because of some pun or metaphorical connection with desired traits. The meal typically begins with a drink of *otoso*, a sweet, spiced sake. A sweet life is further ensured by eating such foods as small candied fish or chestnuts in a sweet potato comfit. Red snapper (*tai*) is eaten because its name recalls the word *omedetai* (auspicious). Sweetened black beans (*mame*) are eaten to become hard working (*mame*) in the new year. A kind of seaweed, *kombu*, is eaten because it sounds like the word for being happy (*yorokobu*). Special chopsticks made of willow are often used at this meal so in the new year the family members will be as flexible in body and mind as a willow tree.

The single most important dish of this meal, however, is the soup, called *ozooni*. Many regional variations of this soup exist. In eastern and northern Japan (including Tokyo) it is typically a clear soup with a few vegetables, while in the west (including Kyoto and Osaka) the soup is made with white miso. Regardless, if it is soup for New Year's morning that has *mochi* in it, it is called *ozooni*. This pounded rice paste, *mochi*, is considered the very essence of rice (Ishige, 2000, p. 1176). Since for centuries rice was a food for the elite and a traditional offering to the Shinto deities, to eat rice essence helps begin the new year right. Traditionally *mochi* is eaten instead of rice for the first three days of the year. Besides being eaten in soup, it is also boiled and dipped in a mixture of sugar and powdered soybeans (*kinako*) or grilled, wrapped in small strips of nori seaweed, and dipped in sweetened soy sauce.

## CONTEMPORARY ISSUES IN JAPANESE CUISINE

The twentieth century, and a few decades preceding it, was for Japanese cuisine a time of diminishing contrasts and increasing variety. During this period the food habits of the Japanese people advanced in two opposite directions. On the one hand, the dietary practices thus far restricted to the urban population spread to all areas of the country. On the other hand, it was a time of revolutionary change in the range of available foodstuffs and in applied cooking techniques. Never before had foreign food infiltrated Japanese cuisine to such an extent as it did during the twentieth century.

### The Making of a National Cuisine

By the 1950s, the abundant regional variety and sharp class distinctions in diet that had been characteristic of premodern Japan gave way to a relatively homogeneous cuisine. The discrepancy between the sophisticated meals of the elite, the simple fare of the townsfolk, and the meager nourishment of peasants gradually faded away. Although the trade in local specialties flourished under the rise of capitalism, regional flavor had become by the late twentieth century the exception rather than the rule in the dietary culture of the Japanese people (Noguchi, 1994, pp. 323–326).

Urbanization has been largely responsible for the blending of regional food habits in modern Japan. The migration of great numbers of Japanese to Korea, Manchuria, and other colonies, and their repatriation after 1945, contributed to it as well. Modern food preservation technologies, such as canning and freezing, along with the popularization of foreign food, also played an important role in making the Japanese diet uniform. The increasing impact of mass media and home-economics education, as well as rising living standards, were other crucial factors in this process.

First of all, the rice-centered meal pattern consisting of a serving of rice, a bowl of soup, pickles (*tsuke-mono*), and side dishes had by the mid-twentieth century become a national standard. This pattern developed around the thirteenth century in the kitchens of wealthy warriors and monks, spread to less affluent samurai and townspeople during the following centuries, but only became the norm in peasant households in the wake of World War II. The daily diet of the rural population of Japan had thus far been composed of hearty soups; various types of millet, buckwheat, and barley, rather than rice, were their staples. Although rice has, since ancient times, been the most important crop in Japan, forming the center of its economy, a rice-based diet has for centuries been unattainable for the majority of the population (Ohnuki-Tierney, 1993, pp. 30–43).

The same holds true for soy sauce—nowadays regarded as the prevalent Japanese flavoring, the essence of Japanese cuisine. It should be mentioned that before the modernization of the country began in the late nineteenth

century, peasants constituted more than 80 percent of the population. It is only since the beginning of the twentieth century that soy sauce has become affordable for every Japanese family. Before this shift took place, soybean paste (*miso*) had been the principal flavoring in farm households. Along with the factors mentioned earlier, the increased efficiency in production and retailing of soy sauce in the twentieth century helped it assume the position of Japan's national condiment.

### Multicultural Eating

World War II is generally regarded as the watershed between the traditional and modern culinary culture in Japan. The food shortage of the 1940s diminished dietary prejudices, the American Occupation (1945–1952) instigated a powerful Westernizing influence, and the 1960s economic boom provided the means for the majority of the population to re-create affluent meals of the past and to mimic foreign food fashions (White, 2002, pp. 64–73).

Indeed, the economic affluence of the 1970s and 1980s supported extensive Westernization of Japanese food habits. A clear decrease in rice, soybean, and fish consumption, and a concomitant rise in red meat, dairy, and wheat consumption is just one of many indicators of this shift.

The year 1971 serves as a symbolic point marking the beginning of Japan catching up with the rest of the world in culinary culture. In that year the first McDonald's outlet was opened in Tokyo, soon followed by other American fast-food chains, ice-cream parlors, and steak-houses. The late 1980s and early 1990s witnessed the rise of the so-called ethnic food (*esunikku ryori*) boom. The ethnic-food category encompassed a variety of South and Southeast Asian cuisines as well as other culinary rarities such as Caribbean and Ethiopian cooking. This interchange of trends has turned Japanese cities into multicultural melting pots, hardly different in this respect from their counterparts elsewhere in the world. French, Italian, Chinese, Korean, and Indian are ubiquitous geographical headings on restaurant billboards in contemporary Japan.

Not only the restaurant culture underwent extensive transformation during the last decades of the twentieth century. Japanese home menus are less adventurous, yet by no means do they lack foreign influence. Most foreign dishes are incorporated as side dishes into the rice-centered meal pattern with soup and pickles. Dishes such as curried rice, spaghetti, and Chinese-style fried noodles are exceptions to this rule as they already constitute a meal.

The school lunch system, introduced in 1947 by the Allied Occupation authorities as a means of improving the nutrition of Japanese children, had a profound impact on the Westernization of Japanese home cooking. School lunches differed markedly from the typical Japanese meal in their strong emphasis on bread and milk, often combined with Western-style dishes such as curry

stew, hamburger steak, spaghetti with meat sauce, and salad (Ehara, 1999). The kinds and combinations of foods served at school not only influenced children's tastes, but also indirectly affected the meals served in their homes. The postwar generations of children raised on such school lunches have grown into adults with tastes distinctly different from those of their parents and grandparents. The mass media and home-economics education provided Japanese women with the skills and expertise to satisfy the new food tastes of their families.

### Accommodating Foreign Food

Although internationalization of Japanese cuisine has been proceeding rapidly from the 1960s onward, it was not entirely a product of post-World War II decades. The first signs of Western influence could already be seen in the late nineteenth century, soon after the opening of Japanese ports to foreign trade and the launch of a series of social and economic reforms.

Young Japanese prefer to drink beer and eat *yakomono* (grilled foods) rather than more traditional dishes. Grilled chicken and fish (shown here) are among the most popular. PHOTO BY ANDRÉ BARANOWSKI.

The first Western-style restaurants in Japan opened in the 1860s in port towns that were designated to receive foreign ships and accommodate Western settlements. These restaurants were at first targeted exclusively at Western clientele. With the growing popularity of Western-style dining among the Japanese upper classes, however, Western-style restaurants began to cater to the Japanese customer as well. By the late 1880s, each provincial city in Japan had at least one Western-style restaurant, and within the next few decades a great many Western-style diners (*yoshokuya*) mushroomed throughout the country. They provided less affluent Japanese citizens with domesticated versions of Western-style dishes, such as fried fish, beefsteak, veal cutlet, croquettes, omelets, and stew. These dishes were not served as components of set menus consisting of several courses, as was the general practice at more expensive establishments, but were to be ordered à la carte and usually served accompanied by a plate of Japanese-style boiled rice. For the working classes, these Western-style diners were their only opportunity to try food that was different from what they usually had at home. Western-style cookery was not to enter Japanese folk kitchens until several decades later.

The early twentieth century did witness, however, the rise of a hybrid style of Japanese-Western home cooking among the nouveau-riche class of white-collar urban professionals. Middle-class housewives looking for diversion in their domestic chores ardently embraced this new eclectic cuisine (Cwiertka, 1998, pp. 49–54). Next to Western-style dishes, Chinese-style recipes began to be prominently featured in household literature from the 1920s onward—a decade after cheap eateries run by Chinese immigrants became popular in Japanese cities. Western and Chinese cooking techniques such as pan-frying, stewing, and deep-frying of breaded meat and fish enlarged the variety of Japanese cookery. By the 1930s, the Japanese-Western-Chinese culinary triptych was firmly established as the foundation of modern Japanese foodways. The incorporation of Western-style and Chinese-style dishes into the diet of the Japanese armed forces contributed greatly to the popularization of this new food among all segments of society (Cwiertka, 2002, pp. 7–15).

### Food Safety

From the 1970s onward, when rice-centered cuisine had reached the entire population and was about to be challenged by the encroachment of foreign food, a concern about sufficient food supply gradually shifted toward food safety (Jussaume, Hisano, and Taniguchi, 2000). Consumer awareness about the risks of food contamination and the connection between environmental pollution and food production grew steadily. In 1973, the National Association of Consumer Cooperatives (now known as the Japan Consumer Cooperatives Union) began to emphasize food safety in its marketing strategies. Various consumer groups advocating organic farming and reduction of food imports became active all over Japan. The issue attracted wide public attention in the late 1980s and early 1990s, when pressure from the United States and some European countries to open Japan's rice market met with violent opposition in Japan. A current example of the mainstreaming of the food-safety movement is the fact that the Japanese public strongly opposes genetically modified foods despite assurances from the Japanese government about their safety.

With the first Japanese case of bovine spongiform encephalopathy reported in 2001, and an increase in the incidence of child obesity and coronary diseases, it seems that Japanese consumers have not only added Western foods to their menus, but now have some of the same worries about food as Europeans and Americans.

**JUDAISM.** Jewish food is primarily defined by the dietary laws of Judaism. The Judaic religion is prescriptive in the selection, cooking preparation, and consumption of specific food items. Daily practice is meticulously structured to comply with Jewish law, the Halakhah, and the community of Jews is organized as a community of religiously complying eaters. Specific dishes, food combinations, and cooking preparations are prescribed for religious festivals. Throughout their history of multiple migrations and diaspora (dispersion), the Jews have been in contact with different cultures, languages, and cuisines. This has generated a diversified Jewish cuisine.

### Dietary Laws

Under the classifying terminology of kosher versus nonkosher, the system of dietary prescriptions and prohibitions in Judaism primarily involves the consumption of animal flesh, and is codified in the Pentateuch, in Leviticus (chapter 11). Typical edible animals are domestic, have a vegetarian diet, and are physiologically "plain," that is, not affected by any disease or anatomical or physiological defect. In fact, as Mary Douglas has pointed out in *Purity and Danger*, the dietary prohibitions of Leviticus include a biblical narrative logic. They are organized along the mythological lines that structure the cosmological section of Genesis. Thus the animal kingdom is classified into three categories: those living on the earth, those living in the water, and those living in the air. In the first category, only mammal quadruped ruminants with split hooves are allowed on the Jewish table. Striking exceptions to this rule are emphatically mentioned in the text. Among the animals living on the earth, the swine, the camel, the hare, and the rock-badger are specifically excluded from the Jewish table because they satisfy only one condition for edibility; that is, either they are a ruminant, or they have a split hoof, instead of both

Ceramic bucket for kugel and steamed pudding. Saarland, Germany, circa 1890–1915. Used in cooking classes of the *Verein für Fraueninteressen* (Women's Topical Club) in Landau, Germany, until about 1918. The club membership was largely Jewish. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

conditions required. The category of animals living in the air also functions as an exclusive system, when it provides a list of animals strictly prohibited on the table. Most of these animals are carnivorous birds, while the bat is eliminated for being a flying mammal, an utmost abomination by the Leviticus standards. Finally, animals living in the water should have fins and scales to be considered "pure" and edible, while those crawling on the earth or living underground are also considered "impure."

In addition to these dietary prohibitions concerning the selection of animals based on anatomical and physiological criteria, biblical law forbids the consumption of blood (Deuteronomy 12:23) and the mixture, in the kitchen and at the table, of dairy foods and meat dishes (Exodus 23:19). The former rule thus requires the strict observance of slaughtering techniques designed to evacuate the largest amount of blood from meat cuts before they are distributed to the marketplace. Some secular scholars have interpreted the regulation of Jewish food practices by religious law and sacred scriptures as evidence that the idea of God is at the core of the Jewish table. This spirit, although viewed by some as being motivated by hygienic concerns, has generated a complex system of community institutional organization that involves the technical training of rabbinical slaughterers (*shohatim*), their appointment in slaughtering houses, and the establishment of a system of verification of the

The 1910 edition of Josephine Gumprich's *Complete Practical Cookbook for the Jewish Kitchen*, which first appeared at Trier, Germany, in 1888. This book was popular with Jews in Europe and ran through several editions. ROUGHWOOD COLLECTION.

enforcement of dietary laws. The latter requirement is often handled by secular agencies, in collaboration with local rabbinical authorities. In New York, for example, the presence of the largest urban Jewish population in the world has generated a system in which the state government is in charge of the enforcement of kosher laws in the local food stores, especially those selling meat displayed as being kosher (Fried, 2000).

### Jewish Festival Foods

At the core of all Jewish festival tables is the sanctified bread, or challah. Oven-baked and usually excluding dairy ingredients, the loaves are braided, though other shapes can be found in various Jewish traditions. Another typical festive dish is the Ashkenazic gefilte fish (Yiddish, "stuffed fish"), opening sabbath or holiday meals as a

good omen. Most holiday menus are linked to the religious festivals and have a narrative function. Examples include the fried pastries served during Hanukkah. The holiday of Hanukkah is a ritual celebration of the biblical section narrating the Maccabees' victory over the Seleucid Greeks in the second century B.C.E. and the following miracle that kept the ritual oil lit for eight days in the Second Jerusalem Temple after it had been devastated by the Greek armies. Thus, in the Jewish communities of central and eastern European origin, the tradition requires that latkes, fried potato pancakes, be served. The equivalent in the Jewish traditions of the Mediterranean and the Middle East is usually fried buns served with honey. Purim celebrations include the baking of multiple pastries, a playful reminder of the defeat of Haman. Thus, Ashkenazic families serve *hamantaschen* or "Haman's hats," poppy seed-filled triangular pastries.

The Jewish festival of Passover, a ritual narration of the Jewish slaves' exodus from Pharaoh's Egypt, includes special food prescriptions. During the eight days of the holiday, the only bread allowed for consumption is unleavened bread, to commemorate the bread that the slaves took in their hasty overnight flight from slavery. This unleavened bread, called matzo in Hebrew, is industrially baked today as a thin square flat cracker according to the Ashkenazic (eastern and central European) tradition. In Sephardic (Mediterranean and Middle Eastern) traditions, matzo has a round shape. The Passover food restrictions also require that no leavened substance be included either in the kitchen and menus or in the household at all. Some North African Jewish communities exclude rice from their Passover diet. Some also exclude chicken for fear of finding grain in the gizzard. Thus most Passover pastries and carbohydrate dishes are prepared with matzo flour or cracked matzo. Ashkenazic Jews traditionally serve matzo balls boiled in chicken soup, matzo brei (a fried, egg-coated matzo pancake), while North African Jews often enjoy the flavors of a couscous made out of cracked matzo.

Shavuot, or festival of the Torah, is marked by the consumption of honey and dairy foods, with which the Torah is allegorically identified. *Blintzes*, cheese pancakes, are displayed on Ashkenazic tables, while Sephardic traditions include yogurt or *baklava*. The favorite dishes served for Rosh Hashanah (Jewish new year) include heavily sweetened dishes such as the Ashkenazic *tzimmes* (a sweet carrot and raisin stew) and honey cake, all of which are designed to welcome a good and sweet new year. The fall festival of Sukkoth (also Sukkot) includes *borsht*, a beet and cabbage-based soup, served in households of Polish origin.

### Sabbath Foods

The Jews' food history is characterized by their many migrations and their status as a minority group. From this viewpoint, it is as diverse as Jewish cultures, languages, and community experiences have been, as Jews have re-

lated to the multiple cultures and populations they have been in contact with throughout the world. Jewish food has operated, both practically and symbolically, and not unlike Jewish languages, as Jewish versions of local nutritional habits. An illustration can be found in most dishes served for the most important holiday of the Jewish ritual calendar, the Sabbath. The *tsbulent* is the Ashkenazic version of this sabbatical dish. The Yiddish name of this dish includes two French words, *chaud* ('warm') and *lent* ('slow'), a linguistic combination testifying not only to the many influences on Jewish culture and languages, but also to the specifically Jewish character of this dish's cooking technique. It is in effect cooked slowly for about twelve hours between the beginning of Sabbath (Friday night) and the Saturday lunch. This long and slow cooking is the result of the sabbatical prohibition on lighting fire during the twenty-four hours between Friday night and Saturday night. This implies that once the Sabbath candle is lit on Friday evening, any food starting to cook then will end up being overcooked when it is consumed on Saturday. In North Africa and the Middle East, this dish is called by either of the Arabic terms *dfina* or *tfina* ('buried'), *skhina* or *hammin* ('warm'). The first set of terms refers to the burying of the pot underneath blankets or even in an underground oven designed to keep warmth in. The second set of terms refers to the permanent warmth of the dish. All Sabbath dishes are composed of heavy and varied ingredients found in the local marketplace: beef, grain, potatoes, vegetables, peas or beans. In eastern North Africa, the tradition was to use green vegetables such as spinach or Swiss chard, fresh fava beans, or cardoons. This ingredient use is probably a custom borrowed from local Muslim neighbors. Muslims of these regions serve very green dishes for major holiday dinners, in the belief that green was the Prophet's favorite color. Thus local Jews have integrated this color symbol into their own major holidays.

The many migrations that have affected the Jews of eastern Europe, North Africa, and the Middle East throughout the twentieth century have resulted, in the early twenty-first century, in the massive secularization of the Jewish migrants in the hosting countries. Traditional Jewish food has thus become a marker of ethnic identity rather than a part of religious observance. On the other side, these traditional dishes, because they are the last ritual items to be given up in the process of Jewish secularization, constitute practical and social frameworks allowing religious observance to be maintained, even in its minimal scope.

**KELLOGG, JOHN HARVEY.** John Harvey Kellogg (1852–1943) was born in Tyrone, Michigan. When he was four years old, his family moved to Battle Creek, Michigan, where his father was one of the founders of the Western Reform Institute, a Seventh-Day Adventist health clinic specializing in hydrotherapy ("the water cure") and vegetarianism. The Seventh-Day Adventists were the largest American religious denomination to endorse vegetarianism. Kellogg enrolled at Bellevue Hospital College in New York after completing his undergraduate work, where he studied medicine. In 1876, upon completion of his studies, Kellogg took over administration of the Western Reform Institute. He subsequently changed its name to the Sanitarium and enforced a strict vegetarian culinary regimen. Under his guidance, the Sanitarium was visited by America's rich and famous people and Kellogg's beliefs became widely disseminated.

Assisted by his younger brother Will K. Kellogg (1860–1951), John H. Kellogg experimented with rolling, flattening, and baking whole grains. The resulting flakes were a culinary success at the Sanitarium, and the Kelloggs decided to mass-produce and sell them through mail order. Imitators soon sprang up and churned out numerous similar products, including Grape Nuts and Post Toasties developed by C. W. Post, who had been a patient at the Sanitarium. Kellogg's creation had launched the commercial cold cereal industry.

John Harvey Kellogg also rolled other products, such as nuts, thus creating nut butters, which he believed were a substitute for cow's butter. While nut butters were made from all available nuts, peanuts were the least ex-

Photo portrait of John Harvey Kellogg. COURTESY AP/WIDE WORLD PHOTOS.

pensive nut. The Kelloggs created the Sanitas Nut Food Company, and again Will was placed in charge. Due in large part to the efforts of the Kellogg brothers, peanut butter quickly became an American favorite.

To develop further the commercial possibilities, the Kelloggs incorporated the Toasted Corn Flake Company in 1906. John H. Kellogg was the majority stockholder, but he distributed part of this stock among the Sanitarium doctors. Will Kellogg bought up the stock until he personally owned the majority of shares. Will promptly put his signature on the box and renamed the company that was ultimately to become Kellogg Co. To enhance sales, Will added sugar and other additives to the recipe and increased sales through advertising not as a health food for the ill, but as an enjoyable and convenient breakfast food for everyone. The two brothers went through years of legal battles over the name, but in the end Will won. For years the brothers never spoke to each other.

Later, John Harvey Kellogg confronted a variety of other problems. About 1906 the Seventh-Day Adventists excommunicated Dr. Kellogg and eventually severed ties with the Sanitarium. However, he survived until the Depression hit, and the Sanitarium began to lose money. It

continued in operation until 1942, when it was sold. Kellogg died the following year.

Will Kellogg remained as president of the Kellogg Company until 1929, but remained as chairman of the Board until his death in 1951. In 1930 he established the W. K. Kellogg Foundation in Battle Creek, one of America's foremost philanthropic institutions.

**KITCHEN GADGETS.** One of the earliest recorded uses of the term "gadget" was in 1886 as a nautical term referring to a small, somewhat specialized contrivance. It is unclear when the term first entered kitchen parlance, but the *Oxford English Dictionary* records the earliest use of the expression "kitchen gadget" as 1951 in the *Good Housekeeping Home Encyclopedia*, which remarked that kitchen gadgets are often discarded because it takes too much time to clean them.

A popular contemporary taxonomy of kitchen technology must account for the essential ambiguity of the term. Terms like "gadget," "utensil," "accoutrement," "tool," and "appliance" overlap. A kitchen gadget may be a specialized artifact used for the preparation of a single kind of dish or for performing one specific function across a variety of dishes. As such, it can be distinguished if only in a general sense from the broader term "kitchen utensil," which would include multipurpose and essential kitchen equipment, such as chefs' knives and large appliances like ovens and refrigerators. In modern usage the term "kitchen gadget" also may be pejorative. It is often used to refer to novelty items, gimmicky and cheap kitchen equipment that purports to ease the burdens of homemakers. As the usage in the *Good Housekeeping Home Encyclopedia* indicated, gadgets may be the kinds of products that accumulate in the back of kitchen drawers until they are discarded. Another aspect of the gadget is its symbolic character. Gadgets may be displayed as items that represent taste, newness, or status.

Although the term "gadget" originated in the late Victorian era, it is often used retroactively to refer to pre-Victorian forms of specialized kitchen equipment. Pro-

viding an account of early kitchen tools is difficult as such items rarely made their way onto household inventories. It is well established that, apart from the kitchens of the aristocracy, pre-Victorian cookery, at least in the British Isles, was almost entirely a matter of boiling in a pot, cauldron, or kettle; baking in an oven or on a bake stone; and roasting on a spit. A number of devices were designed to assist the pre-Victorian cook with each of these kitchen tasks.

### Victorian Gadgets

The jack was one of the most useful Victorian aids. Roasting spits, also known as “broches,” “peakes,” or “flesh pikes,” were mounted in the fireplace. A jack is a device that rotates the roasting spit without the constant attention of the cook. A great variety of techniques for spit rotation were designed over the years. The earliest jacks relied on a system of weights akin to those in a weight-driven clock for their slow and steady movement. Another early form of jack was the smokejack, first imported into England from Germany in the second half of the sixteenth century. The force of air and smoke rising in the fireplace chimney powered this kind of jack. Perhaps the most unusual were the animal-powered jacks, which relied on animals, such as dogs or geese. Geese were considered a better source of power, as dogs quickly became bored with the work and were far craftier than geese at shirking their duties. The most popular kind of jack was the windup or spring jack, which the Swedish botanist and noted traveler Pehr Kalm observed in almost every English home he visited in 1748.

Another kitchen implement from this era was the tin roaster. In its earliest form, a piece of wood lined with reflective tin was placed next to the meat to reflect the heat back and increase cooking efficiency. This arrangement evolved into a small and elegant device that only occupied the width of the fire bars. The tin roaster consisted of a tin enclosure to reflect heat back onto the meat, a dripping pan, and a door on the front through which the cook could baste and otherwise attend to the meat. Tin roasters often incorporated that other essential roasting gadget, a windup or bottle jack.

Another common kind of hearth-front gadget was the toaster. Hearthstones, a variety of toasting forks, and hinged devices mounted on the side of the hearth were all used to toast bread. One of the more common devices was the hearth toaster, a long-handled piece of cast iron that held the bread between small arches that could be swiveled to toast both sides of the bread.

Boiling and simmering called for some arrangement to regulate temperature by shifting pots closer to or farther away from the fire. The most basic technique used a series of pothooks or hangers of varying lengths. Another technique used a chain wrapped around a rod so it could be rotated. The chimney crane was perhaps the most elegant of these devices. The rod and hook techniques could only be used to move a pot up and down,

whereas the chimney crane could move a pot through three dimensions. This afforded much more precise heat regulation than the hook or rod techniques and allowed the cook to move the pot out of the fireplace without directly picking it up. The chimney crane saw wide use, especially in southeastern England from the sixteenth century through the eighteenth century.

Within the great houses, an altogether more sophisticated battery of kitchen equipment existed. For example, inventories of the British estate Ham House from the 1670s and 1680s list sixty-two kinds of items. This list includes such specialized equipment as a tin apple roaster, colanders, a tin grater, a three-chain jack, a fish kettle and a carp pan with false bottoms, numerous larding pins, several mortars and pestles, pastry peels, a “rolling” (rolling) pin, skimmers, lark spits, iron toasting tongs, a wooden whisk, and a sieve (made of hair) along with the sundry common items like knives, pots, pans, and skillets.

The list of items at Ham House includes a number of “basons” (basins) of undesignated use. It is a safe assumption that they may be freezing basins. Hannah Glasse published several editions of *The Art of Cookery Made Plain and Easy* from 1747 on. Each edition included instructions for making ice cream using two pewter basins, one with a tightly fitted lid enclosed within the larger basin. She suggested two kinds of basins. One, manufactured in France, was tall and cylindrical; the other was three-cornered and wedge-shaped. The wedge basin was used with three other identically shaped basins so the cook could make a multihued circle of ice cream.

During the Victorian era, the use of the hand-cranked ice cream machine became widespread. The English inventor William Fuller sold a pamphlet titled *A Manual Containing Numerous Original Recipes for Preparing Neapolitan Ices* along with a hand-cranked machine patented in 1853. The machines of Fuller and his competitors were popular with professional confectioners and the wealthier and innovative set. They were not in common use at the household level. The first hand-cranked machine was patented in the United States in 1848, and domestic versions were available in the 1860s. By the 1880s numerous hand-cranked machines were designed for the domestic market, and many were still available in the early twenty-first century. The basic ice cream machine is a coopered wooden bucket into which an enclosed rotating chamber is inserted. A hand crank rotates the chamber. The chamber is surrounded by ice and salt, which reduces the chamber’s temperature low enough to congeal its contents.

Some of the characteristic beliefs of modernity are that everything can be known and that all nature can be mastered if one applies sufficient time, expertise, and specialized technology to the task. This positivism was the prevalent mindset of the Victorian era. It should come as no surprise that the term “gadget” originated in the 1880s as the Victorian era saw an immense explosion in the

**TABLE 1**

<b>Gadgets and their requisites</b>	
<b>Gadget</b>	<b>Requisite</b>
Jack: weighted	Hearth
Jack: smoke	Hearth and flue
Jack: windup or bottle	Hearth
Jack: animal-powered	Hearth and obedient dog or goose
Tin roaster	Hearth
Toaster	Hearth or for modern forms electricity
Pothooks and hangers	Hearth
Chimney crane	Hearth
Tin apple roaster	Hearth
Ice-cream maker: manual	Ice, salt, and muscle power
Ice-cream maker: electric	Electricity and either ice and salt or a refrigerator with a freezer compartment
Eggbeater	Muscle power
Stand mixer	Electricity and a variety of attachments, such as a whisk, flat paddle, or dough hook. Numerous other gadgets can be powered by a stand mixer, such as can openers, slicers and shredders, food grinders, fruit and vegetable strainers, grain mills, citrus juicers, pasta makers, and sausage stuffers.
Cafetiere	Ground, roasted coffee and hot water
Espresso maker	Hot water or electricity and finely ground, roasted coffee beans
Goblin	Electricity and tea
Coffee grinder	Electricity and roasted coffee beans
Coffee roaster	Electricity and raw coffee beans
Percolator	Electricity or alcohol for heat and roasted coffee beans
Drip coffee machine	Electricity, filter, and roasted coffee beans

development of small and highly specialized tools. This proliferation of specialized technology existed across all spheres of human activity, including the domestic, where kitchen gadgets flourished. The number of kitchen gadgets invented or in widespread use for the first time during the Victorian era was immense.

A book like Isabella Beeton's *The Book of Household Management* (1861) was representative of this Victorian positivism. Beeton set out in 1,112 pages to inform the homemaker how to micromanage every aspect of domestic economy. Her list of thirty-seven essential kitchen utensils, including a bread grater, was far more involved than the kitchen inventories of most British households in the preceding century.

This era saw the invention of many new kitchen gadgets, including the apple peeler, other specialized peelers, the mechanical eggbeater, the mechanical dough mixer, bread toasters, potato mashers, coffee grinders, food choppers, and waffle irons. The African American

inventor John Thomas White was issued a patent for a lemon squeezer in 1896. It consisted of two pieces of wood connected by a hinge. The bottom piece included a slotted opening so the juice of the lemon could pass through when the two pieces were squeezed together.

### Modern Gadgets

Many modern kitchen gadgets are simply updated and electrified forms of kitchen gadgets developed in the Victorian era. The aforementioned home ice-cream makers are representative of this trend. In the 1950s electric models of the ice-cream maker were introduced. The earliest models simply replaced the hand crank with an electric motor. Models from the late 1960s were designed to fit into a refrigerator freezer. In the 1960s the two most prevalent kinds of contemporary ice-cream makers were developed. The relatively inexpensive prefreeze models featured an insert filled with refrigerant that was pre-frozen in the refrigerator freezer. The second kind of ice-cream maker used a small, built-in freezer to congeal the ice cream or sorbet.

The toaster is another updated item. The first electric toasters were built in the early twentieth century immediately after the invention of a nickel and chromium alloy, trademarked as NiChrome, was used to make the first high-temperature electric heating elements. The first commercially viable electric toaster was the General Electric D-12, an open affair mounted on a ceramic base. Electrical toasters underwent a number of innovations, including metal and plastic enclosures and various slot sizes to accommodate changing tastes in bread. Toasters designed specifically for bagels have become common. The combination toaster and oven was popular in the 1980s, but its acceptance has steadily declined due to its general ineffectiveness at both toasting and performing the duties of a small oven.

The toaster oven is one of the more widespread representatives of the multiple-function gadget. The numerous representatives of these devices range from the ill-fated combination nutmeg grater and corkscrew patented by George Blanchard in 1856 to the kitchen equipment advertised on late-night television that can do "all this and so much more." Perhaps the most successful multipurpose kitchen gadgets are the appliances manufactured by companies like Bosch, KitchenAid, and Sunbeam derived from the 1884 eggbeater design of the African American inventor Willie Johnson. His eggbeater was powered by a driving wheel in conjunction with a system of gears and pulleys that rotated a set of beaters, blades, or stirrers.

The eggbeater was an updated and mechanized version of the kitchen whisk that further evolved into a wide variety of gadgets. One of the most significant was the electric mixer. The first American patent for an electric mixer was filed in 1885 by Rufus W. Eastman. The earliest electric mixers were large, clunky machines that in the twenty-first century would look more at home in a

wood shop than in the kitchen. By the 1930s at least a dozen manufacturers made electric mixers, including the nearly ubiquitous Hobart (KitchenAid) and the Hamilton Sunbeam. The Sunbeam Mixmaster model M4A, which was first manufactured in 1930, was relatively streamlined in comparison to its competitors. Its name "Mixmaster" eventually became the generic term for a stand mixer.

The new stand mixers were not really gadgets so much as constellations of gadgets. The Sunbeam Mixmaster was advertised as capable, given the right attachments, of mixing, mashing, whipping, creaming, stirring, beating, extracting fruit juice, chopping, grinding, and blending. A twenty-first century advertisement for the KitchenAid Stand Mixer lists attachable accessories that include a can opener, a rotor slicer and shredder, a food grinder, a fruit and vegetable strainer, a food tray, a grain mill, a citrus juicer, a pouring shield, a pasta maker, a sausage stuffer, a flat beater, a dough hook, and a whisk.

Coffee and tea have inspired quite a few gadgets over the years, including kettles, cafetieres, espresso makers, goblins, grinders, roasters, percolators, and drip machines. The tea goblin or the teasmade is one of the more unusual kitchen inventions. This was a British invention of the 1930s that made tea on a timer. Goblins often featured alarm clocks, lamps, heating elements, and devices for placing the tea into the hot water. Coffee was traditionally prepared by the Turkish method of boiling the coffee until the development in 1806 in Germany of the percolator by the American Count Rumford, who saw coffee drinking as an alternative to the hard-drinking lifestyle of German workers. The drip coffee maker soon followed. Early models were heated by burning alcohol, replaced by electrical elements in the early twentieth century. Other inventions included the steam espresso maker, which forces steam through the ground coffee until it is condensed on the other side, and the cafetiere, of which the most popular model worldwide is the Danish Bodum. Americans have preferred drip and percolator models, and Italians have preferred espresso makers that rely on various mechanisms, from pressurized cylinders to straight steam pressure, to force steam through the coffee grounds.

Coffee and espresso makers have accumulated attachments to much the same extent as the stand mixer. The difference lies in the purpose of these attachments. Coffee and espresso appurtenances are components of the machine designed to complement a cup of coffee rather than to perform a wide range of kitchen tasks. These appurtenances include devices for scalding and frothing milk and grinding coffee built directly into the machine. Some coffee makers emulate the tea goblin. On a timer, they grind the coffee beans, insert the grounds into the filter, and then make the coffee.

Kitchen equipment is tied to representations of status, and coffee-making equipment is an ideal example. The first electric percolators were designed as elegant

table centerpieces, and most coffee was preground and sold in vacuum-sealed tins. By the 1980s percolators were no longer considered the height of sophistication. An elegant North American coffee drinker used a drip coffee maker and ground his or her own beans. By the twenty-first century, a European method was preferred. An Alessi-designed cafetiere or an Italian espresso maker, such as one of the pressurized La Pavoni machines, or even a stovetop steam-pressured espresso maker signified good taste.

**KITCHENS, RESTAURANT.** With the debut of executive chef Gray Kunz's \$1 million kitchen at the restaurant Lespinasse in New York City's St. Regis Hotel in 1994, the restaurant kitchen became a showplace and status marker for American chefs. Cast-iron ranges from France, cool-to-the-touch induction stoves from Japan, fast-churning ice-cream machines from Italy have become de rigueur for any cook worth his *fleur de sel*. But despite the push for state-of-the-art technology in kitchen design, the organization of the staff and the layout of the workspace have not changed much since Georges-Auguste Escoffier's day.

#### Kitchen Organization

In addition to codifying and modernizing the culinary repertoire, Escoffier is credited with streamlining the

organization of the kitchen. "I myself have often been forced to make profound changes in my restaurant service to meet the need of the ultra rapid pace of modern life," he wrote in his memoirs at the turn of the twentieth century (p. 119). His solution was a kitchen organization based on principles of efficiency and division of labor that grew out of the Industrial Revolution. The tasks involved in assembling the meal are divided among different "stations" (*parties* in French), each with its team of cooks. The various elements of any finished dish may come from as many as five or six stations. Together, the team of chefs in the kitchen is known as the *brigade*. In English, the chefs who prepare the places during service are known collectively as the line. It is interesting to note that in many kitchens, no matter their ethnicity, French kitchen terms are usually mixed up with whatever language is spoken.

At the top of the kitchen hierarchy is the executive chef. In a hotel, the executive chef oversees all food preparation in the property's various food service outlets; the role is largely administrative. In a restaurant, the executive chef's duties are usually more hands-on. Now that so many restaurant chefs have multiple restaurants under their command, however, their role has also become more administrative in scope. Below the executive chef is the *chef de cuisine*. This is the person directly in charge of managing the kitchen. The cooks all report to the *chef de cuisine*, who in turn reports to the executive chef. To help oversee the smooth management of the kitchen, the *chef de cuisine* usually has one or two *sous-chefs* (literally "under chefs"). The responsibilities of the *sous-chefs* are often divided by meal period—for instance there will be a lunch *sous-chef* and a dinner *sous-chef*. The breakdown of the *chefs de partie*—"station chefs" or "line cooks" in English—is determined by the breadth and scope of the menu (not to mention the space available in the kitchen) and their tasks at hand. Thus, the *saucier* is responsible for making the sauces and stocks. Because of the emphasis Escoffier placed on sauces in his culinary repertoire, the *saucier* traditionally holds an exalted status in the kitchen. The *rôtisseur* is responsible for meats and roasts, the *poissonier*, fish. A *grillardin* does the grilling, a *potager* makes the soups (*potages*, in French). Vegetables and other side dishes are the charge of the *entremetier*. The *friturier* mans the fryer. The *garde-manger* is in charge of the cold pantry, from which issues forth hors d'oeuvres, salads, garnishes, and other cold preparations. During the eighteenth and nineteenth centuries, when large presentation pieces and ornate garnishes were an important element in traditional French service, the role of the *garde-manger* was elevated in status. The *pâtissier* is in charge of the pastries and other baking. A *chocolatier* would be responsible for chocolate items. Further divisions and subdivisions are also possible.

Depending on the demands placed on the staff, within the different stations there may be multiple cooks and assistants. Young apprentices known as *commis* or *sta-*

*giaires* are plentiful in large kitchens, for they are generally strong, eager, and willing to work for little pay. A *tournant* is an experienced chef who can fill in at any station should the cooks become backed-up during service (referred to colloquially in English as "being in the weeds"), or should someone not show up to work.

The expediter (*aboyeur*, in French, or "barker") is the person to whom the orders from the dining room are given by the waitstaff or, more likely these days, by the computerized ordering system. This is the role the executive chef often takes during service (often to the dismay of the staff; most executive chefs make poor expeditors). The expediter is responsible for timing the preparation of a table's order so that all of the various components from the different stations are completed at exactly the same moment. This ensures that the food is served at its prime and contributes to the smooth operation of the restaurant and the maximum satisfaction of each guest is an important task.

### Variations among Kitchens

The breakdown of the *brigade* differs from restaurant to restaurant. In reality, only the largest, most expensive restaurants follow Escoffier's organization to the letter, but a surprising number are based on his model. Most kitchens are organized around a compressed version of the traditional hierarchy. With modern technology and convenience foods (of which, based on his memoirs, Escoffier would likely have been a champion), it is possible for as few as three line cooks to turn out hundreds of meals, albeit of questionable quality.

Perhaps the most important factor in determining the organization of the kitchen is the menu, which itself is an outgrowth of the overall concept of the restaurant. The array of dishes, the variety of cooking techniques, and the intricacy of garnishes all have a direct impact on the way the kitchen functions. In planning the menu it is imperative that the chef consider the impact new items will have on each station of the kitchen. The second most important factor in the design of the kitchen and the division of labor is the physical layout of the space. No matter how heavy the demands placed by the menu on a particular station, if there is not enough space for the cooks to work comfortably, efficiency will suffer. Kitchens also reflect the personality and management style of the chef in charge. Some chefs prefer to divide stations based on the natural divisions of the menu. Thus, you will sometimes hear stations referred to by the terms "hot apps" (hot appetizers) or "salads."

Different styles of cuisine require different divisions of labor. In Italian restaurants, the pasta station becomes supremely important. In seafood restaurants, naturally, multiple fish cooks are required. Some types of cooking require a different organization altogether. Chinese restaurants are able to offer a vast number of dishes because of the way the kitchen is set up. Each chef has a workspace with at least one wok (usually several) and a

The classic restaurant kitchen drew for its inspiration upon the structure and labor organization of the royal kitchens of Europe. Depicted here is the well-organized kitchen of the Hofburg (royal palace) in Berlin in 1861. Note that all the cooks are wearing uniforms that define their station or pecking order in the hierarchy of the kitchen command. ROUGHWOOD COLLECTION.

huge array of ingredients at the ready. One dish at a time is prepared and sent out to the table as it is finished. This accounts for (or results from) a style of eating that is totally different from the Western model. In Japanese restaurants, the cooking is sometimes done right in front of the guests by the principal chef and his assistants. Although in the West we are familiar with this set-up in sushi and *teppanyaki* restaurants, in Japan other types of restaurants are molded into this configuration. Exemplary Mexican, French, and Italian restaurants in Tokyo are set up according to this sushi-bar model.

Although the “open kitchen” concept became popular in restaurant design in California in the 1980s and has since spread throughout the country, these kitchens, which afford diners a peek into the inner workings of the restaurant, are usually organized according to the traditional French model, not the Japanese. Similarly, the rise in popularity in the 1990s of “chef tables”—dining tables actually located in the thick of the kitchen commotion—offer an up-close view of the fine-dining kitchen.

Some American chefs make a point of shunning the traditional hierarchical organization of the kitchen alto-

gether. The two most renowned are probably Alice Waters at Chez Panisse in Berkeley, California, and Barry Wine at the former Quilted Giraffe in New York City. Both chefs pride themselves on the democratic ideology that governed their kitchens, giving each cook a more or less equal say in the decision-making process. Although the reasons behind the adaptation of this democratic model were very different—Waters came out of the Berkeley hippie movement of the 1960s and 1970s; Wine aspired to have the most innovative and creative restaurant in the high-flying 1980s—both succeeded in producing world-class restaurants that attracted international acclaim.

### Social Interaction

Because of the high-pressure environment of most restaurant kitchens, they act as crucibles of social interaction. Despite formidable attempts to organize the kitchen into a smooth running “assembly line,” systems and chains of command often break down. George Orwell’s *Down and Out in Paris and London* (1933) offered a vivid glimpse of life in a large Parisian kitchen at the

beginning of the last century. Some seventy-five years later, the grit of kitchen life has again captured the popular imagination, with tell-all books such as Anthony Bourdain's *Kitchen Confidential* (2000) topping bestseller charts. In *Kitchens* (1996), sociologist Gary Fine offers a more scholarly portrait of kitchen life. Fine produced an ethnographic sociological study of work and human interaction in the restaurant kitchen environment. Fine spent several months in the kitchens of four restaurants that covered the spectrum of dining establishments from chain to fine dining. His study examines kitchen life through the filters of economic, class, and aesthetic considerations. He notes:

[Cooks] face enormous challenges, toiling in an environment less pastoral than infernal. Cooks must ready the kitchen several hours before customers arrive, not knowing precisely how many to expect. Preparation must permit flexibility, depending on the walk-in trade and last-minute reservations. They must then be ready to cook numerous dishes, simultaneously and without warning, with sufficient speed that those with whom they must deal—servers and ultimately diners—do not become frustrated. Cooks have several masters. Restaurants are both service and production units, and, so, cooks work simultaneously for customers and management (p. 19).

Fine's findings emphasize the importance of the organization of the kitchen on the overall success of the restaurant and on the satisfaction derived from those who work in the restaurant kitchen environment.

**KOREA.** Owing to the popularity of Korean barbecue (*kalbi* and *pulgogi*) outside Korea, Korean cuisine is often thought of as meat-based when compared with other Asian cuisines. However, in essence it has for centuries depended largely on vegetables and, to a lesser degree, on seafood. In fact, the consumption of animal products (beef, pork, chicken, eggs, milk, and dairy products) in Korea increased more than twenty times in the last three decades of the twentieth century, mainly due to economic affluence.

Chinese, Japanese, and Western (particularly American and Italian) influences are becoming increasingly visible, especially outside the home. Yogurt and Western-style sweets have become the staples of Korean children, and American fast-food chains (McDonalds, KFC, and Pizza Hut), particularly popular among the youth, are successively enlarging their share of the Korean restaurant market. Koreans of older generations prefer Chinese restaurants, which have been popular for several decades, to the more recent Japanese and Italian establishments. Chinese food is often cooked at home as well.

Yet, despite all these foreign influences, the daily fare of most Koreans, outside or inside the home, still consists of rice, soup, and side dishes—a meal structure that has barely changed for centuries.

#### The Korean Meal

There are few differences among the food Koreans consume at each meal. Supper is usually more elaborate than

breakfast and lunch, but generally speaking, every meal is centered on plain boiled rice (*pap*), soup (bouillon-like *kuk* or a more hearty *t'ang*), and pickled vegetables (*kimchi*). Side dishes (*panch'an*) extend this core, and their number depends on the occasion. Three to five side dishes are the norm in contemporary households.

Stews (*tchigae*, *tchim*, *chŏn'gol*) and soured or sautéed greens (*namul*, *pokkŭm*) constitute the majority of side dishes, complemented by grilled dishes (*kui* or *sanjŏk*) made of seafood, beef, pork, or chicken. Stews tend to acquire the position of a semi-main dish, as does *pulgogi*, turning into a center of the meal accompanied by a bowl of rice, smaller *panch'an*, and dipping sauces. Big-bowl dishes such as fried rice (*pokkŭmbap*), beef soup with rice (*sŏlŏngt'ang*), and mixed rice (*pibimbap*) are served in a similar fashion, with small portions of greens and pickles on the side.

Rice boiled or steamed with beans, other grains, or vegetables may be served instead of plain boiled rice. A variety of wheat and buckwheat noodles (*kuksu*) also frequently appear on the Korean table. Noodles are usually served in soupy liquids, while stuffed dumplings (*mandu*) can be either steamed, panfried, or simmered in soups (*manduguk*). Noodles and dumplings are popular lunch dishes. Flavored rice porridges (*chuk*) are less commonplace than rice, noodles, and dumplings, but still retain a notable place in Korean cuisine.

Chili pepper, sesame (seed and oil), garlic, and spring onions, along with soy sauce (*kanjang*), soybean paste (*toenjang*), and red bean paste (*koch'ujang*) constitute what might be called a Korean “flavoring principle.” The combination of all or a selection of these ingredients gives Korean dishes their characteristic taste. Ginger, semi-sweet rice wine (*ch'ŏngju*), and honey or sugar are the other crucial components of the Korean flavor.

### **Kimchi**

Pickled vegetables, generally referred to by the name of *kimchi*, are the most basic, indispensable element of every Korean meal. Neither a feast nor a most meager fare would be complete without it. For centuries *kimchi* was the sole side dish to accompany the staple of Korea's poor, whether it was barley, millet, or, for the fortunate few, rice. It was also a fundamental meal component in affluent households. Three kinds of *kimchi* were always served, regardless of how many side dishes were to appear on the table. To a contemporary Korean, rice and *kimchi* are the defining elements of a minimal acceptable meal. Yet, it is *kimchi*, not rice, that is regarded as the symbol of Korean culture.

There are hundreds of varieties of *kimchi*. Every region, village, and even family used to cherish its own special recipe, applying slightly different preparation methods and using slightly different ingredients. Napa cabbage (*Brassica chinensis* or *Brassica pekinensis*) made into *paech'u kimchi* is the most common type, followed by

radishes (*Raphanus sativus*) made into *kkaktugi kimchi*. Basically, vegetables are placed for several hours in brine, washed with fresh water, and drained. Then, flavorings such as ginger, chili pepper, spring onions, garlic, and raw or fermented seafood are added, and the mixture is packed into pickling crocks and allowed to age.

Since the 1960s, when factory-made *kimchi* appeared on the market for the first time, the number of urban families who continue to make their own *kimchi* has gradually diminished. With the rising consumption of meat and seafood, and the popularization of Western-style food, the quantity of *kimchi* consumed by Koreans has declined as well. An average Korean consumes approximately forty pounds of *kimchi* on a yearly basis.

Yet, *kimchi* is still considered to be the most important element of the Korean meal and quintessentially Korean by Koreans and foreigners alike. Despite this cultural symbolism, *kimchi* has evolved relatively recently to the form we know today. The so-called “white *kimchi*” (*paek kimchi*), which is still popular in the early twenty-first century, resembles most closely the original version.

The addition of chili pepper came about in the mid-eighteenth century and gave *kimchi* its characteristic red color and pungent taste. Fermented seafood (*chŏtkal*), which has been included in the pickling from the late nineteenth century onward, not only enriched the taste of *kimchi*, but also increased its regional diversity. While at the end of the seventeenth century only eleven types of *kimchi* were classified, the regional variety of *chŏtkal* (some regions use shellfish, others anchovies or other kinds of fish) contributed to the development of several hundred varieties of *kimchi*. The type of vegetables that are pickled also changed. Gourd melon, cucumber, and eggplant have been used since ancient times; today napa cabbage and radish are the most common varieties.

### **The Table Setting**

With a few exceptions, all components of the meal are on the table at one time. A set of a spoon and metal chopsticks is used while eating. Rice, soup, and other liquids are eaten with the former, side dishes with the latter. Soup and rice are served in individual bowls, but side dishes are often shared by more than one diner. Nowadays, bowls are usually made of stoneware, steel, or plastic, but for special occasions white porcelain tableware is used. In the past, the upper classes dined from brass bowls in the winter and porcelain ones during the hot summer months. A silver set of chopsticks and a spoon was considered most elegant. Less affluent sections of the population generally dined from earthenware, using wooden chopsticks and spoons. According to Korean etiquette, it is considered inelegant to lift bowls from the table. They stay on the table during the entire meal, unlike in the rest of East Asia, where it is customary to lift bowls up to the mouth while eating.

The majority of restaurants in Korea have two dining areas: one with Western-style tables and chairs, and one with an elevated floor where customers seated on cushions dine at low tables. Similarly, most Korean households use Western-style tables with chairs on a daily basis (the table is usually placed in the kitchen), but share meals at a low table with short legs, seated on cushions laid on the floor, when guests are entertained.

The most traditional dining setting is a small table designed for one or two persons. In upper-class households, there was no common dining room and such tables were laid in the kitchen and carried out to different parts of the house, where family members dined, divided according to age, gender, and position. Such dining arrangements reflected the hierarchical ideology of pre-modern Korea. The shared dining table with short legs became popular in the early decades of the twentieth century and by the 1960s spread all over the country, widely replacing the ubiquitous individual table. This transition was followed by the diffusion of Western-style table and chairs in the 1980s. Yet, even today, traditional tables designed for one are still used in some restaurants, student apartments, and average Korean households.

### Food and Drink for Special Occasions

From the fifteenth century onward, Confucianism began to replace Buddhism as the strongest cultural influence in Korea. Various festivals and their celebration in Korea are closely related either to Buddhism or to Confucianism. These events are always marked by special food, with noodles, red beans, and many kinds of rice cakes playing a prominent role in festive meals and snacks. Because Korean meals traditionally did not include desserts, festivals were among the few occasions when sweet snacks were served, except in upper-class families, where sweet afternoon snacks were regularly prepared.

Throughout the ages, each festival food has acquired a symbolic meaning or a function that justifies its use at a specific occasion. Noodles, for example, are appropriate for birthdays because they symbolize long life. Red-bean porridge (*p'atbuk*) with sweet rice balls (*kyōngdan*) eaten on the day of the winter solstice is said to prevent colds and drive away ghosts. Colorful rice cake (*mujigae ttōk*) is prepared for a child's first birthday in the hope that the child will enjoy a wide range of accomplishments.

Certain occasions are inseparable from the food that is served during their celebration. The Harvest Moon Festival (*Ch'usōk*), for example, is unimaginable without pine needle-scented rice cakes (*songp'yōn*), and lunar New Year's Day celebrations (*Sōllal*) would not be complete without rice cake soup (*ttōkkuk*). "How many bowls of rice cake soup have you eaten?" is a polite way of asking about someone's age, as if failing to eat a bowl of rice cake soup would deprive a person from a complete New Year's experience.

Garnishing (*komyōng*) is taken very seriously in traditional Korean cooking and becomes especially pro-

nounced in festival food. Three-color garnish is made with egg yolk (yellow), egg white (white), and Korean watercress (green). Five-color garnish includes these with the addition of chili pepper threads (red) and stone-ear mushrooms (black).

Drinks are another medium used to celebrate special occasions. *Porich'a*, scorched-rice tea made by boiling water over the rice that sticks to the bottom of the cooking pot, used to be the most important daily beverage in Korea. Today, along with water, it remains an important drink to accompany meals. For celebrations, most Koreans drink either *soju* or beer. *Soju* is a kind of distilled liquor made of grain or sweet potatoes, with an alcohol content of up to 45 percent. Although it is often claimed to have been introduced to Korea in the thirteenth century through trade with the Mongols and Chinese, it is not clear whether the contemporary version has any connection with its ancestor apart from the name. Beer was introduced by the Japanese in the late nineteenth century and began to be produced on a large scale in the early 1930s.

A large variety of homemade wines (which are strictly speaking ales) flavored with ginseng, pine needles, chrysanthemum, cherry, plum, or apricot blossoms, herbs, and fruits were popular before the turn of the twentieth century. The ban on homemade wines during the Japanese colonial period (1910–1945) had a devastating effect on this part of the Korean tradition. The use of rice for wine making continued to be prohibited after the liberation, due to the shortage of rice. The ban on rice wine was lifted in 1971, and various efforts have been undertaken since to revive local wine making in Korea. In 1985, for example, the government designated many traditional wines as cultural assets. *Makkōlli*, a milky rice wine with an alcohol content of 6 to 8 percent, also known under the name "farmer's wine" (*nongju*), is one of the most popular alcoholic drinks in contemporary Korea.

Alcohol is never drunk in Korea without elaborate snacking. Practically all side dishes can be served for this purpose and are called *anju* at such occasions. *Anju* can be small like French hors d'oeuvres or Spanish tapas but are not always small. Stews and large savory pancakes (*chōn*), including vegetables, meat, and seafood, are typical snacks to accompany drinking.

### The Historical Overview

The foundation of Korean cuisine was formed between the seventh and thirteenth centuries, with important modifications taking place in the eighteen and nineteenth centuries. As was the case with other aspects of Korean culture, Korean cuisine developed under the strong influence of its powerful neighbor—China. As in adjoining regions of East Asia, rice and fermented soybean products (soy sauce, soybean paste, and soybean curd) occupy a prominent place in the diet of the Korean people. The "rice-soup-side dishes" structure of the meal and the use of chopsticks to consume it are other indicators of the

Korean men celebrating the traditional Confucian New Year, which includes both prayers and food. Photographed 1 January 1988 in Seoul, Korea. © NATHAN BENN/CORBIS.

impact that Chinese civilization exerted on Korean foodways. The emphasis on five elements in Korean cuisine, for example, five flavors (salty, sweet, sour, hot, and bitter) and five colors of garnish, has Chinese origins as well. It should be emphasized, however, that despite this heritage, Korean cuisine has developed into a distinctive entity of its own, with more differences from Chinese cuisine than similarities to it.

The technology of rice cultivation was brought to the northern parts of the Korean peninsula from China, probably late in the second millennium B.C.E., but rice became a staple of the Korean diet only in the Silla period (668–935 C.E.). In fact, before the second half of the twentieth century, rice was not a staple for everyone, but was rather a symbol of wealth. The old phrase “white rice with meat soup,” for example, connotes the good life, while tacitly acknowledging that not everyone could afford either rice or meat. Millet, barley, and buckwheat accompanied by *kimchi* and vegetable soup were the daily fare of the majority of the Korean population.

Vegetarian Buddhist influences in Korea did not, apart from the clergy, have much impact on food habits. Beef, pork, lamb, chicken, and various types of game were regularly consumed by the Korean upper classes. Still, before the economic growth of the 1970s, the eating of meat was a luxury for the common people in Korea. Farmers, who formed the majority of the Korean population, rarely ate meat except for three days in summer when dog stew was served and a special day in winter when sparrow, wild boar, or wild rabbit was prepared. In

both cases, the eating of meat was intended to strengthen physical resistance to extreme weather conditions (Walraven, 2002).

The techniques for making wine and *chang* (a semi-liquid predecessor of soy sauce and soybean paste) were also introduced from China, and by the seventh century were already highly advanced. This was also the time when fermented seafood (*chōtkal*) developed, along with vegetables preserved in salt. The latter eventually evolved into *kimchi* pickles.

Chili pepper was brought to Korea at the end of the sixteenth century, most probably via Japan. It became widely cultivated a century later and by the twentieth century was an integral part of Korean cuisine. As well as being an indispensable component in *kimchi* making, chili pepper contributes to the flavoring of the majority of Korean dishes through chili pepper powder (*koch'u karu*) and red bean paste (*koch'ujang*). Both are not only used extensively in the kitchen but often appear on the table as a relish.

It should be mentioned that the extensive use of chili pepper, and consequently the pungent taste of Korean cooking, was not originally characteristic of all Korea, but rather a feature of the Kyōngsang province occupying the southeastern part of the peninsula. The diet of the southwestern provinces and the territory covering contemporary North Korea used to feature less spicy dishes than was the case in Kyōngsang. Urbanization and the development of modern transport and communication networks led to the gradual decline of regional differences

Street vendors in Kyoonggi-do, South Korea, peel and chop vegetables to prepare kimchi, a spicy cabbage relish served with most Korean meals. © MICHAEL FREEMAN/CORBIS.

in the Korean diet. These differences, however, have by no means completely disappeared. Ch'ŏrwŏn, for example, is famous for *makkŏlli* wine, Ch'unch'ŏn for its chicken barbecue (*talkkalbi*), and Hamhung province for its cold noodles (*naengmyŏn*). The cooking of the southwestern provinces tends to be generally less spicy than the rest of the country. Chŏlla province, in particular, tenaciously retains its culinary distinctiveness.

Along with a gradual decline in regional differences and the democratization of the Korean foodways, the twentieth century marked the time of the modernization of production, processing, distribution, and consumption of food in Korea. This started during the Japanese occupation and continued in South Korea after the Korean War (1950–1953).

The Japanese introduced modern farming techniques and Western-style food processing. The railway system and the highway network erected by the colonizer led to the centralization of markets and modernization of retailing. Japanese and Korean physicians created the foundation of Korean dietetics, and affluent Korean women got acquainted with the Western science of nutrition through Western-inspired Japanese home economics education.

After the Korean War, South Korea continued to modernize under the strong influence of the United States. American dietary influences have become particularly visible since the 1980s but have not been widely welcome. While foreign products are desirable for the status and novelty they impart, the Korean people generally disapprove of the country's growing reliance on food imports (Pemberton, 2002; Bak, 1997). The increasing consumption of meat, for example, led to a rise in the number of livestock in Korea, making this mountainous country with almost no pasture largely dependent on imported feedstuffs. This and similar issues play an important role in the dietary consciousness of the Korean population today.

**KOSHER LAWS.** See *Judaism; Passover*.

**KWANZAA.** Unlike December holidays steeped in centuries-old traditions, Kwanzaa, the African American year-end feast, was not established until 1966 by Maulana Karenga, a cultural nationalist. The celebration, which occurs annually from 26 December to 1 January, is based on a compilation of several harvest festivals and celebrations from around the African continent. During the holiday week most Kwanzaa celebrants use a menu of traditional African American dishes, foods from the "mother continent," and foods from the African diaspora. The word "Kwanzaa" comes from the Swahili expression "matunda ya kwanza," meaning 'first fruits of the harvest,' but the American Kwanzaa is distinguished from the African one by the addition of a second "a" in the second syllable.

The holiday was originally celebrated by cultural nationalists who wished to express pan-African solidarity. In the intervening years, however, it has become a rapidly growing tradition with over 18 million people of all political leanings and in all walks of life celebrating the week following 26 December as a time of feasting, fasting, and self-examination.

The holiday is not designed as a replacement for or alternative to any of the other year-end festivities like the Christian Christmas, the Jewish Hanukkah, or the Hindu Divali (Festival of Lights, celebrating Lakshmi, the goddess of wealth; also called "Diwali" or "Dewali"). Rather, it is a time for reflection and self-examination that can replace or be celebrated jointly with any or all of the year-end holidays.

The celebration of Kwanzaa is guided by the *Nguzo Saba*, the seven principles of self-awareness, so each day

Dancer dressed as Chi Wara, the antelope who represents New Year at a Kwanzaa festival in Leimert Park, Los Angeles. COURTESY AP/WIDE WORLD PHOTOS.

of the week-long festival is devoted to the celebration of one of the building blocks of self-awareness.

Umoja—Unity

Kujichagulia—Self-Determination

Ujima—Collective Work and Responsibility

Ujamaa—Cooperative Economics

Nia—Purpose

Kuumba—Creativity (The feast of karamu is held on this day and is a public celebration at which the community gathers to celebrate the holiday.)

Imani—Faith

The number seven is at the core of the celebration. There are seven days, seven principles, and seven symbols of the holiday. The *mazao* are the fruits of the harvest that are a part of the celebration table, and the *mkeka* is the mat on which they are arranged. The *kinara*, the seven-branched candlestick, holds the *mishumaa saba*, the seven candles (three red, three green, and one black) that are lit every evening: first the black candle, symbolizing the people, and then, alternating, the red and green candles, symbolizing the principle that without struggle, there is no attainment.

Each Kwanzaa table has a centerpiece. On each centerpiece there are *mubindi* (also *vibunzi*), ears of corn, one for each child in the family who is still at home. If there are no children in the family, there is a single ear to remind the celebrants that, in the words of the proverb, "it takes a village to raise a child." The *kikombe cha umoja*, the chalice of unity, is the cup that is passed around or from which the ceremonial libation is poured. Finally, there are the *zawadi*, gifts, which should be educational and emphasize growth and self-knowledge.

**LABELING, FOOD.** Food products offered for sale in the United States are subject to a number of legal requirements regarding what information must, may, and may not appear on the package label. Food labels serve many purposes. The label identifies what the product is and how much of it there is, alerts individuals to the presence of allergenic ingredients, and provides nutritional information to enable consumers to make healthy dietary choices. Many of the regulations governing food labeling are extremely detailed, often specifying the placement and minimum type size of required information.

The term “label” refers to any written, printed, or graphic matter on the food’s immediate container. “Labeling” includes the label and any other written, printed, or graphic matter accompanying the product in commerce (e.g., point-of-sale pamphlets). Most label information is required to appear on either the “principal display panel” (PDP) or the “information panel.” The PDP is the part of the label most likely to be displayed to, and examined by, consumers under customary conditions of retail sale. The information panel is generally the panel contiguous to, and to the right of, the PDP. If that panel is unusable or too small, the next panel to the right of it may serve as the information panel. If the top of the container is the PDP, the information panel may be any panel adjacent to the PDP.

### **Government Agencies and Governing Laws**

The U.S. Food and Drug Administration (FDA) is the federal government agency that administers and enforces labeling requirements for all foods (except meat and poultry) under the Federal Food, Drug, and Cosmetic Act (FD&C Act) and the Fair Packaging and Labeling Act. The U.S. Department of Agriculture (USDA) administers and enforces labeling rules applicable to meat and poultry products under the Federal Meat Inspection Act and the Poultry Products Inspection Act. While the FDA does not require, or offer, prior approval of food labels, the USDA requires government approval of most meat and poultry product labels prior to their use in U.S. commerce.

Other federal agencies play a role in regulating food labeling as well. The U.S. Customs Service requires country-of-origin marking on the labels of imported food

products. The U.S. Treasury Department’s Bureau of Alcohol, Tobacco, and Firearms (BATF) regulates the labeling of alcoholic beverages. The Federal Trade Commission (FTC) regulates the advertising of food products.

Federal law preempts inconsistent state laws in most areas of food labeling, but there are some aspects of labeling where states may and do impose their own requirements. For example, some states have promulgated their own labeling requirements regarding safety warnings, use-by or sell-by dating, and religious dietary laws.

***General prohibition against misbranding.*** Federal law provides that a food product may be deemed “misbranded” if any part of its labeling is false or misleading. This general provision establishes misbranding even where no specific regulatory requirement has been violated. A food also may be deemed misbranded if any required information is not presented prominently enough—that is, likely to be read and understood by the ordinary consumer under usual conditions of purchase and use.

### **Mandatory Label Information**

***Statement of identity.*** The statement of identity (i.e., the name of the product) must be presented on the PDP. Both the FDA and the USDA have regulations establishing “standards of identity” for certain foods. These regulations prescribe the composition of a food and specify the name of the food to be used in labeling. For example, a food composed of tomato concentrate, vinegar, and spices must be identified as “catsup,” “ketchup,” or “catchup.” However, not all statements of identity are dictated with such specificity. For any given product, the statement of identity is one of the following:

1. The name of the food as specified in any applicable federal law or regulation, such as a standard of identity (e.g., “ketchup”) or a federal common or usual name regulation (e.g., “peanut spread”)
2. The common or usual name of the food, established by common usage (e.g., “French toast”)
3. An appropriately descriptive term (e.g., “hard candy”)
4. A fanciful name commonly used by the public when the nature of the food is obvious (e.g., “candy corn”).

Label (circa 1910) for a can of fancy lima beans showing the food product on one side and the company trademark on the other. While these old labels are attractive graphically, food labeling has evolved considerably since that time, with a full listing of ingredients, nutritional analysis, bar codes for scanning the price, and even country of origin. ROUGHWOOD COLLECTION.

**Net quantity of contents.** The net quantity of contents must be presented on the PDP of the food label in measures both English avoirdupois (i.e., ounces, pounds, etc.) and metric (i.e., liters, grams, etc.). For meat and poultry products, the net contents declaration is required to appear only in avoirdupois measure.

**Nutrition facts.** The amounts of certain nutrients present in one serving of the food product must be presented in the “nutrition facts” panel. Similar products have the same serving size so that consumers can easily compare nutrient levels. Nutrition facts must state the serving size (i.e., the size of one serving) and, unless the product contains only a single serving, the number of servings in the package. Generally, the following nutrients must be declared: calories, calories from fat, total fat, saturated fat, cholesterol, sodium, total carbohydrate, dietary fiber, sugars, protein, vitamin A, vitamin C, calcium, and iron. If other vitamins or minerals are added to the food, they also must be declared.

The graphic requirements for nutrition facts are highly detailed. Nutrition facts generally must appear on the PDP or the information panel. They must appear on the same panel as the ingredients list and the signature line, unless there are space constraints.

Raw fruits and vegetables and raw seafood, which frequently are sold in unpackaged form, are exempt from mandatory nutrition labeling. Instead, the twenty most frequently consumed varieties of fruits, vegetables, and seafood are subject to voluntary nutrition labeling guidelines that apply to retailers of these products. Single-ingredient raw meat and poultry products are likewise subject to a voluntary, retail-level nutrition-labeling program. It should also be noted that restaurant and food-service foods are exempt from nutrition-labeling requirements.

**Ingredients list.** Each ingredient present in a food product must be listed by its common or usual name in

descending order of predominance by weight. While most ingredients must be identified by their specific name, use of generic names is permitted for certain ingredients (e.g., “spices,” “natural flavor”). Special rules apply to the listing of certain types of ingredients. For example, chemical preservatives must be listed by their name, followed by a description of their function—such as “BHT (a preservative).” Certified color additives must be identified by their specific name (e.g., “Yellow 5” or “FD&C Blue 1 Lake”), but color additives not subject to certification may be listed using a generic term (e.g., “artificial color”) or a specific name followed by a description of its function (e.g., “caramel color”).

An ingredient that itself contains two or more ingredients must be listed in one of two ways:

1. By declaring the common or usual name of the ingredient followed by a parenthetical listing all of its components—for example, “milk chocolate (sugar, cocoa butter, milk, chocolate liquor, soy lecithin, vanilla),” or
2. By listing each component of the multicomponent ingredient without declaring the multicomponent ingredient itself—for example, “sugar, cocoa butter, milk, chocolate liquor, soy lecithin, vanilla.”

The ingredients list may appear on either the PDP or the information panel, but it usually appears on the information panel. It must appear on the same panel as the nutrition facts and the signature line unless space constraints prevent such placement.

**Signature line.** The name and place of business of the manufacturer, packer, or distributor is typically called the “signature line” and must be presented on the same panel as the ingredients list and nutrition facts (usually the information panel), unless space constraints preclude such placement. If the name is not that of the manufacturer, it must be preceded by a qualifying phrase stating the firm’s relation to the product (e.g., “manufactured for”

or “distributed by”). The signature line must include a city or town, state (or country, if outside the United States), and ZIP code (or mailing code if outside the United States). A street address must be provided unless the firm is listed in a current city or telephone directory.

### Label Information Required in Specific Cases

In specific circumstances—particularly when additional information could protect or otherwise benefit the consumer—specialized labeling may be required.

**Warning and information statements.** Certain products are required to present warning or information statements on their labels. For example, foods containing the artificial sweetener aspartame must bear the following statement in capital letters: “phenylketonurics: contains phenylalanine.” Other food products required to bear warning or information statements on their labels include the following:

1. Foods that contain the fat replacer olestra
2. Foods that contain the artificial sweetener sorbitol (daily ingestion of 50 grams or more)
3. Foods that contain the artificial sweetener mannitol (daily ingestion of 20 grams or more)
4. Foods that contain dry psyllium husk and that bear a health claim linking consumption of soluble fiber from psyllium husk with reduced risk of coronary heart disease
5. Irradiated foods
6. Fresh eggs (in consumer packages)
7. Foods packaged in self-pressurized containers and intended to be expelled from the package under pressure
8. Foods that contain, or are manufactured with, chlorofluorocarbon or other ozone-depleting substances
9. Juices or juice-containing beverages that have not been processed so as to produce a minimum five-log (i.e., 100,000-fold) reduction in the most resistant pathogen of public health significance (e.g., *E. coli*) likely to occur in that product
10. Meat and poultry products that require special handling to maintain wholesomeness
11. Foods that contain any meat or poultry that is not ready-to-eat.

**Juices.** Certain categories of food products are subject to special labeling requirements. Among the most commonly consumed of such products are the numerous varieties of juices available on the market. Any beverage containing fruit or vegetable juice is required to present a percent juice declaration (e.g., “100 percent juice” or “contains 50 percent orange juice”). This declaration must appear near the top of the information panel and is usually placed directly above the nutrition facts. If a beverage contains less than 100 percent juice and its state-

ment of identity includes the word “juice,” it must also include a qualifying term such as “drink,” “beverage,” or “cocktail.” If one or more of the juices in the product is made from concentrate, the statement of identity must be qualified with the words “from concentrate” or “re-constituted.”

**Country-of-origin marking.** Imported foods are required to bear country-of-origin marking (e.g., “product of Italy”). Country-of-origin marking must appear in a conspicuous place and as legibly, indelibly, and permanently as possible. Placing country-of-origin marking immediately beneath the signature line is often ideal. If the signature line states a U.S. address, it should be followed by country-of-origin marking to avoid misleading consumers about the product’s geographic origin.

**Flavor designation.** If the label (other than in the ingredients list), labeling, or advertising for a food makes a representation (such as by words or pictures) about the food’s primary recognizable flavor, that flavor is considered its “characterizing flavor” and must accompany the statement of identity on the PDP.

**Nutrient content claims.** If a food product’s label includes a relative nutrient content claim (e.g., “reduced fat,” “light,” or “added calcium”), the nutrient content claim must be accompanied by information identifying the reference food and explaining how much the nutrient in question has been reduced or added. In addition, use of certain nutrient content claims triggers the need to include additional nutrient declarations in the nutrition facts. For instance, a claim about potassium content triggers the requirement to declare the actual potassium content in the nutrition facts.

### Optional Label Information

**Nutrient content claims.** A nutrient content claim is any representation that characterizes the level of a nutrient in a food product (e.g., “low fat,” or “sugar free”). A nutrient content claim must comply with the specific criteria for that particular claim. For instance, to make a “low fat” claim, a food must contain three grams or less total fat per reference amount customarily consumed (RACC). (The RACC, as established by the FDA, is the amount of food normally consumed per eating occasion by persons four years of age or older.)

A label statement about the actual amount or percentage of a nutrient in a food (“5 grams of fat per serving”) is permitted, provided it is truthful and not misleading and does not characterize the level of the nutrient in the food. If the statement implicitly characterizes the level of the nutrient (“just 5 grams of fat per serving”), it is an implied nutrient content claim and must either meet the requirements for the implied nutrient content claim (“low fat”), or bear a disclaimer that the food does not meet those requirements (“just 5 grams of fat per serving, not a low-fat food”). Statements such as

“contains the same amount of potassium as a banana” or “as much calcium as milk” are permitted, provided the reference food qualifies as a “good source” of the nutrient and the labeled product has at least an equivalent level of the nutrient per serving.

**Health claims.** A health claim is any representation that characterizes the relationship between any substance and a disease (such as coronary heart disease) or health-related condition (such as hypertension). A “substance” is a specific food or component of a food. A health claim must either be authorized by FDA regulation, or be an accurate representation of a current “authoritative statement” of a scientific body of the U.S. government with official responsibility for public health research related to human nutrition (e.g., the National Institutes of Health). Health claims based on an authoritative statement require premarket notification to FDA—an example is the FDA-approved health claim regarding the substance potassium and the conditions hypertension and stroke. Since 2001 the FDA has authorized the following health claims by regulation:

**TABLE 1**

<b>Health claims authorized by FDA</b>	
<b>Substance</b>	<b>Disease or Health-Related Condition</b>
calcium	osteoporosis
sodium	hypertension
dietary fat	cancer
saturated fat and cholesterol	coronary heart disease
dietary fiber in grains, fruits, and vegetables	cancer and coronary heart disease
soluble fiber from specific food sources (e.g., oat bran, oatmeal, psyllium husk)	coronary heart disease
fruits and vegetables	cancer
folic acid	neural tube defects
sugar alcohols	dental caries
soy protein	coronary heart disease
plant sterol and stanol esters	coronary heart disease

USDA regulations currently prohibit meat and poultry products from bearing health claims.

Like nutrient content claims, health claims must comply with both general requirements applicable to all health claims and specific criteria for the particular health claim being made. For example, to be eligible to bear a claim about soy protein and risk of coronary heart disease, a food must contain at least 6.25 grams of soy protein per RACC, must qualify as a low-cholesterol and low-saturated-fat food, and must qualify as a low-fat food.

To bear a health claim, a food may not contain disqualifying levels of certain nutrients—total fat (13 grams), saturated fat (4 grams), cholesterol (60 milligrams), or sodium (480 milligrams)—per RACC or per labeled serv-

ing. Under what is known as the “jelly bean rule,” a food making a health claim must contain per RACC, prior to any nutrient addition, a minimum level of at least one of the following nutrients: vitamin A (500 international units or more), vitamin C (6 milligrams or more), calcium (100 milligrams or more), iron (1.8 milligrams or more), protein (5 grams or more), or dietary fiber (2.5 grams or more). The purpose of the so-called jelly bean rule is to prevent a food of little nutritional value from bearing a health claim simply because the food has been fortified. Reasonably, the health claim that links sugar alcohols to dental caries is exempt from the jelly bean rule.

The wording and placement of health claims are highly regulated.

**Structure and function claims.** A truthful statement that a food or any ingredient helps maintain a structure or any function of the body may be made in labeling (e.g., “cranberry juice may help maintain a healthy urinary tract”). The manufacturer or distributor making the claim must have scientific evidence supporting the claim.

**Other claims.** A number of other claims that may be made on food labels are also regulated. The FDA has requirements for claims that a food is “fresh” or “healthy.” The USDA has regulations defining “organic.” The FTC limits the use of the claim “new” to a period of six months after a product is introduced into the market. Provided the information given is truthful and not misleading, a food may bear a claim about the presence of an ingredient perceived to add value (“made with real fruit”) or about the absence of a nonnutritive ingredient (“no preservatives”).

**Symbols on food labels.** Food labels may bear a variety of symbols or logos. Some of these are required. For example, irradiated whole foods are required to carry the radura symbol (i.e., the international symbol of food irradiation, which resembles a flower in a circle), and all meat and poultry products are required to bear the USDA official inspection mark. Other symbols are optional. These include the Uniform Product Code (UPC; the most familiar bar code) and symbols indicating that a food product is kosher.

**Recipes and miscellaneous information.** Food labels may carry a wide variety of other optional items, including such things as recipes, promotions, and “romance copy” (e.g., information extolling the virtues of a product or describing its history). Such information is permitted, provided it is truthful and not misleading.

### **Prohibited Label Information**

Any information that is false or misleading in any particular will render a product misbranded. In determining whether a food label is false or misleading, both affirmative representations and omissions of material facts may be considered. Certain information is clearly prohibited from the labeling of food products. This includes unau-

thorized nutrient content claims (for instance, claiming “high in omega-3 fatty acids”), health claims not authorized by FDA or supported by an authoritative statement, and disease claims (for instance, claiming “helps lower blood pressure” would subject a product to regulation as a drug).

### Language Specifications

All mandatory label information in the United States must appear in English. If labeling includes foreign language words of a type that are likely to bring the product to the attention of consumers who do not understand English, then all mandatory information must appear in both English and the foreign language. Certain foreign language words will not trigger dual-language labeling—for example, an accepted name for which there is no English equivalent (such as “antipasto”), a foreign name used in a standard of identity (such as “spaghetti”), and the use of one or more foreign language words in a brand name, motto, or trademarked design.

In Puerto Rico and other U.S. territories where the predominant language is other than English, the predominant language may be substituted for English, except in the case of the USDA inspection mark on meat and poultry products, which must appear in English.

**LACTATION.** Lactation refers to the ability of mammals, warm-blooded, backboned animals, to nourish their young with milk produced by the mammary

glands. Many other distinguishing features separate mammals into families that include over four thousand species. The milk of each species is specifically engineered for the growth and developmental needs of that species. In fact studies of the characteristics of the milk can predict the growth rate of both body and brain and the developmental maturity of the offspring at birth. It is also possible to predict the feeding patterns that vary from the whale, which feeds its young every three to four days and has extremely high-fat milk (50 percent), to the human, who initially feeds the infant every two to three hours and has low-protein, low-fat milk (3.4 percent). Some of the world’s finest scientists have turned their attention to human lactation and have not only deciphered the micronutrients of human milk but have studied the nutrient needs of the human infant, especially as they pertain to brain development and physical growth. Research also has explained the physiology of human lactation.

Historically, in times of wealth and prosperity, women of higher socioeconomic levels have sought substitute feedings for their infants to “free” themselves of the burden of breast-feeding. Dogma and ritual have developed in different cultures of the world around nursing. It is significant that the Qur’an states that women should nurse their infants for two years. In the Old Testament, the Book of Psalms refers to the value of mother’s milk. Pope John Paul II stated that the women of the world should provide their milk for their infants.

When bottle-feeding became more available for the average mother due to the discovery of sterilization, followed by the availability of prepared formulas, the trend toward bottle-feeding increased from 1930 to 1950. Well-educated women led the march to the bottle because they wanted to raise their infants by the book, with scientific information. In the second half of the twentieth century, these same educated women sought a different mode of childbirth in which the mother was prepared and in control. Concomitant with this, well-educated women began looking at breast-feeding as the most appropriate course for their infants.

In 1978 a bipartisan congressional committee charged with the responsibility of designing a health plan for the United States established the year 1990 as the target date for accomplishing several health goals. In addition to statements regarding decreasing hypertension, obesity, and smoking, the committee stated that 75 percent of women should leave the hospital breast-feeding and at least 35 percent should still be breast-feeding at six months. Many of the goals were not accomplished, and in 1990 they were rewritten with a target date of 2000. In 2000 they were rewritten for 2010, aiming at 75 percent of mothers initiating breast-feeding, 50 percent continuing for six months, and 25 percent continuing for a full year. The World Health Organization Code for Infant Feeding was developed in 1981, and the most industrialized countries of the world endorsed this policy, which supported breast-feeding and rejected the

promotion of artificial feedings and advertisement of these feedings to the public. The United States did not sign until 1994. The Institute of Medicine, through the Subcommittee on Nutrition during Lactation, confirmed the position that all women, under ordinary circumstances, should breast-feed their infants and further stated that breast-feeding was ideal, even if the mother's diet was not perfect. The American Academy of Pediatrics, joined by the American College of Obstetrics and Gynecology, stated in 1997 that infants should be exclusively breast-fed for five to six months. They further stated that breast-feeding should continue as weaning foods are added through the first year of life and then for as long thereafter as the mother and the infant choose

### **Significance of Breast-Feeding to Health**

Why have all of these important groups spoken out so strongly in favor of breast-feeding? The knowledge that human milk is for the human infant has been accepted for centuries. In the late twentieth century, however, considerable scientific investigation established unequivocally that breast-feeding is associated with a reduced incidence of infection in the infant, including reduced incidences of gastrointestinal, upper and lower respiratory, ear, and urinary tract infections. Immunologic data have shown reduced incidences of childhood-onset cancers, especially lymphoma and acute lymphocytic leukemia. Crohn's disease, celiac disease, and childhood-onset diabetes also are reduced when infants are breast-fed for at least four months. Probably the most dramatic information published in multiple articles is the relationship between breast-feeding and infant development. A study by Niles Newton compared the developmental progress of breast-fed and bottle-fed three-year-olds. Alan Lucas, Ruth Morley, T. J. Cole, and others reported a multisite study that compared premature babies given their mother's milk by feeding tube with infants given premature-infant formula. The group studied them at eighteen months and followed them until seven and a half to eight years of age. The study showed an 8.5-point difference when the data were adjusted for socioeconomic status and education of the mother. The eighteen-year study by L. John Horwood and David M. Fergusson in New Zealand showed a measurable difference at eighteen years of age in school outcomes and behaviors related to whether or not the children were breast-fed in infancy. Although these studies have been criticized for design flaws, many scientists accept their findings. These results are in addition to the compelling psychologic benefit to the mother and the infant in their relationship during breast-feeding.

### **Facilitating the Decision to Breast-Feed**

A mother needs an opportunity to make an informed decision about how to feed her infant. If a mother comes to pregnancy without any information on this process, it is the health care provider's responsibility to see that she is well informed about the benefits of breast-feeding for

her baby, for herself, and for society so she can make a decision that will be optimal.

***The economic benefit of breast-feeding.*** A simple calculation of the cost of buying formula does not reflect completely the monetary benefits of breast-feeding. It costs between \$60 and \$80 a month to purchase infant formula, \$700 to \$1,000 for the first year of life. Careful studies in controlled populations, such as in health maintenance organizations, have demonstrated in multiple reports that infants who are not breast-fed have an increased number of illnesses, visits to the doctor, prescription medications, and hospitalizations compared with their breast-fed counterparts. The estimate per infant of the health care costs not to breast-feed is between \$600 and \$1,000 per year. This estimate does not include the reduction in the onset of chronic illnesses that may last a lifetime, such as diabetes, Crohn's disease, and allergies.

***Benefits to the mother.*** The benefits of breast-feeding to the mother are often ignored. Women who breast-feed return to their prepregnant, physiologic states more rapidly. The uterus involutes, the postpartum blood loss is reduced, and the woman returns to her physiologic weight as well. Among other possible benefits are reduced incidences of long-term obesity, breast cancer, ovarian cancer, and most remarkably long-term osteoporosis. Although breast-feeding is not a contraceptive, it significantly affects the fertility in the childbearing years by suppressing ovulation.

***Establishing lactation.*** Critical information about the mother's potential for a good milk supply is obtained during pregnancy. When the obstetrician does the early examination of the breasts in the first trimester, the breasts should be evaluated with respect to their potential for producing milk. Unusually small, unusually large, asymmetric, or tubular-shaped breasts may pose a problem. Prior surgery of the breast should be discussed. Lumpectomies and augmentation mammoplasty are not contraindications. Reduction mammoplasty, however, may pose a problem if the integrity of the ducts was interrupted. The obstetrician should also evaluate the breasts' responses to the hormones of pregnancy, the degree of increase in size of the breasts, and changes in the areola and nipple. The obstetrician should discuss with the mother her intentions to breast-feed and address any questions she may have. The mother should be encouraged to attend breast-feeding preparation classes, which are commonly available at hospitals with maternity services and at local mothers' groups.

The breast prepares for lactation during pregnancy by enhancing the ductal system and developing lacteal cells that will produce the milk. From about sixteen weeks in gestation on, the breast is capable of making milk if the fetus is delivered. During pregnancy the placenta produces a prolactin-inhibiting hormone (PIH) that blocks the breast from responding to the abundant prolactin of pregnancy. Once the placenta is delivered, the PIH drops,

and the breast responds to the hormones oxytocin and prolactin.

The key response of the breast following delivery is called the ejection or letdown reflex, prompted by two major hormones, oxytocin and prolactin. Oxytocin causes myoepithelial cells to contract. Thus when the baby stimulates the breast by suckling, a message is sent via the peripheral nervous system to the mother's brain and pituitary to release oxytocin, which in turn causes the myoepithelial cells that surround the alveoli and the ductal system to contract, ejecting the milk from the ducts. Suckling at the breast also stimulates the release of prolactin, the hormone that stimulates the lacteal cells to produce milk. Prolactin is not released unless the breast is stimulated. Oxytocin, however, may be released when the mother sees her baby or hears her baby cry or as a result of other stimulating sensory pathways.

It is recommended that the infant be put to breast as soon after delivery as is possible. The infant has been sucking and swallowing in utero, consuming considerable amniotic fluid, from about fourteen weeks gestation on, so he or she is ready to begin breast-feeding.

To put the infant to breast, the infant is held with his or her abdomen against the mother's and the infant looking directly at the breast. The mother supports the breast with her hand, keeping her fingers behind the areola and gently compressing it. The mother strokes the center of the infant's lower lip with the nipple. This stimulates the infant to open his or her mouth, extend his or her tongue, and draw the nipple and the areola into his or her mouth. The baby's tongue compresses the elongated nipple and areola against his or her hard palate. The peristaltic motion of the tongue stimulates the let-down reflex, and milk is released and swallowed. Infants should be fed when hungry, which is eight to twelve times a day initially. No other food or drink is necessary during exclusive breast-feeding for up to six months.

**LAMB.** See **Mammals; Meat; Sheep.**

**LAMB STEW.** Lamb stew is a preparation in which tough cuts of lamb (by definition, taken from a sheep younger than one year of age in Europe or younger than two years of age in the United States, at the time of slaughter) or mutton (lamb's counterpart on the older side of the dividing line) are cut into small pieces, seared in hot fat, and simmered slowly in a flavored liquid until moist and tender; in the process, its liquid medium becomes a glossy sauce rich with the flavors of the meat. The tender, high-status rack portion of the lamb comprises only four percent of its live weight. Most other parts of the meat—leg, shank, shoulder, breast, neck, arm, and trim—increase in both flavor and toughness with the age and activity level of the sheep. Such cuts are best prepared with a method that can at once tenderize the meat, preserve its moistness, and mellow its flavor. Stewing fits these needs particularly well.

Stewing is most effective on older, tougher cuts of meat rich with collagen—a stiff protein found in connective tissue. With ample exposure to sufficiently high temperatures for a length of time relative to the muscle's toughness, slow stewing converts collagen to gelatin, yielding tender bits of meat perfumed with the cooking liquid, and a sauce rich with sheen and body. A simmer just below the boiling point is ideal, as such a temperature is sufficiently hot to make the gelatin soluble over time, yet gentle enough to keep the muscle moist and tender, rather than causing constriction and exudation of most of its juices, as would occur under a rolling boil. Such processes constitute the physical and chemical basis of stewing lamb. The cooks and the influence of the prevailing culture determine whether the stew is made with breast, shoulder, or neck; cooked in a clay, cast iron, or copper-bottom pot; or flavored with rosemary and red wine, dill and lemon, or cardamom and ginger.

A testament to the effectiveness of the stewing method for lamb and mutton (here used somewhat in-

terchangeably, owing to the varied legal definitions) is the plethora of national, regional, and individual variations found in a diverse array of cultures. (See the Table for some of these variations.) Throughout Europe and the Mediterranean, lamb stews are typically flavored with ingredients like wine, garlic, rosemary, thyme, parsley and other herbs, and bacon, onion, carrot, celery, cabbage, tomato, or potato. From northern to southern Africa, lamb stews vary from the Moroccan *tangine* (or *tagine*) to Ethiopian versions with butter and *berbere*, a chili and spice paste, to South African European-style

stews of lamb and legumes. In China, lamb stews are flavored with fermented sauces; in India, they are thickly flavored with spices, nuts, and yogurt, as they are in many other parts of Asia. Throughout much of Oceania and in parts of the United States, where lamb is big business, the stews incorporate flavors from throughout Europe, Africa, and Asia. Even in traditional cuisines of North America, where lamb is a relative newcomer, it is often substituted for indigenous meats, as an example, for alpaca meat in the Andean stew *huatia*.

But it is in the Middle East and the Arab World, more than anywhere else, where lamb stew has the broadest variety of manifestations—from a lamb-and-wheat porridge, to a stew with fresh dill and lemon, to some with red beans or fava beans, or with other legumes, many with apricots and spices, and even more containing tomatoes.

While there is likely no definitive answer as to why lamb stew is so important in the Middle East, there are some strong clues, both material and intangible, that can help to explain its centrality. The most evident reason is that Mesopotamia is the home of the domesticated lamb, with a tradition of raising sheep for wool and meat that goes back more than ten thousand years. Nearly as ancient is lamb’s religious significance: roasted sheep ranked high in status among the early Semitic sacrifices, both prebiblical and biblical; and the paschal lamb of both Passover and Easter underlie references to Christ as the “Lamb of God.” Even today, Christians in the Middle East and Mediterranean traditionally serve roast lamb for Easter; Sephardim serve stewed lamb for Passover; and Arabs serve roast or stewed lamb for nearly every feast—births, marriages, and death anniversaries, in addition to those of strictly religious celebrations.

Moreover, elements of lamb stew indicate some of the shared values of Middle Eastern culture. Societies of the Middle East as well as others consider it good etiquette to serve food in tender bite-size morsels as a display of time, effort, and hospitality on the part of the host, who would not have guests struggle to consume their food. Whole roast lamb is often presented and served off the bone, in contrast to the European tradition of displaying a formidable roasted joint or whole animal. A rich stew of lamb also highlights the accompanying rice, couscous, bread, or grain, accompaniments of simple integrity that complement the richness of the lamb. Many Middle Eastern people also place additional value on the local origins of the sheep, which is considered far superior to imported lamb, beef, or poultry, and is certainly preferred to pork, forbidden among observant Muslims and Jews.

Lamb stew has a deep history and tradition, a common base with seemingly infinite variations, a strong, complex, and pervasive flavor, and firm entrenchment in the surrounding culture. It is often seen as symbolic of the people and region of the Middle East.

TABLE 1

A sample of national and regional variations of lamb stew	
Region/Country, Name(s)	Key Flavoring Ingredients
<b>Europe</b>	
Spain, <i>estufado de cordero</i>	Chorizo sausage and blood sausage, garlic, wine.
France, <i>navarin d'agneau</i> ; <i>printanier</i>	Turnips, root vegetables, wine; spring vegetables.
Norway, <i>lammestuing</i>	Cabbage and peppercorns.
Ireland, Irish stew	Potatoes and onions.
Basque region	Garlic, onions, carrots, potatoes, wine.
<b>Africa</b>	
South Africa, <i>lensieskos</i>	Lentils, ginger, tomatoes, chili, garlic.
Ethiopia, <i>sega wat</i>	Butter, onion, <i>berbere</i> chili and spice paste.
Morocco, lamb <i>tangine</i>	Carrot, chickpeas, spices, garlic, <i>harissa</i> chili paste.
<b>Eastern Asia</b>	
India, <i>kashmiri gosht</i> ; <i>badami gosht</i>	Nuts, yogurt, onions, spices including cardamom, cloves, turmeric, coriander, chilies, saffron.
China, hot pot	Soy sauce, chili paste, garlic, ginger, scallion, rice wine.
<b>Americas</b>	
Native Andean, <i>huatia</i>	Uncultivated herbs, chilies.
Cuba, <i>chilindron de carnero</i>	Bacon, lime, onion, bell pepper, tomato, garlic, cumin, oregano.
<b>Middle East and Arab World</b>	
<i>khoresche estanaj</i>	Lemon, dill, and green vegetables.
<i>keshkeg herriseh</i>	Porridge of lamb and wheat with onion, bay leaf.
Syria, <i>yukhnee</i>	Tomatoes, garlic, onion, spices.
Persia, <i>khoresht qormeh sabzi</i>	Red beans, onion, turmeric, lemon, fresh herbs.
Persia, Armenia, Morocco, and elsewhere	Apricots, garlic, onion, lemon, spices including turmeric, coriander, ginger, cayenne, cumin.
Turkey, <i>pirpirim asi</i>	Assorted pulses, uncultivated greens.
Sephardim, <i>msouki</i>	Onion, garlic, fava beans, fresh peas, <i>harissa</i> chili paste, nutmeg.
Egypt, <i>fatta</i>	Pilaf-style rice and bread with stewed mutton.

**LANGUAGE ABOUT FOOD.** Foods can be named according to different levels of generality. The basic level terms (Rosch, "Principles of Categorization") are the most consistent across languages in that translation equivalents can be readily found. Examples of basic level terms are "apple," "potato," "rice," "coffee," "turkey," "salmon," and "snails." This level often corresponds to scientific taxonomies. More specifically, varietal or breed terms tend to be compounds consisting of a modifier plus a basic term, as in "Jonathan apple," "jasmine rice," "sock-eye salmon," or "green-lipped mussel."

Higher level categories are more variable across languages than are basic level terms and often result in different, incompatible classifications. Whether a tomato is a fruit or a vegetable depends on the purpose of the classification. For scientific purposes, it is a fruit (as are squash and bell peppers), since it contains the seed for reproduction. However, for culinary purposes, a tomato is a vegetable in Europe and North America. In Taiwan, where tomatoes are eaten for dessert, along with sweet fruits, it would be a fruit. English-speakers classify potatoes as vegetables, but German-speakers are not likely to consider the *Kartoffel* (potato) to be included in the German word *Gemüse*, translated as "vegetable" but not co-extensive with the English category.

There are many named categories based on cultural, dietary, and religious practices. According to Jewish dietary laws, the term *kosher* designates foods acceptable for Jews to eat, and *tref* (a Yiddish word) designates pork, shellfish, and other foods forbidden to eat. Another distinction is between *milchig*, describing dairy products, and *fleishig*, describing meat products, which include poultry but not fish. Items from these two categories are not to be eaten at the same meal. *Pareve* products are made without milk or meat, and can be eaten at dairy or meat meals.

Foods can be classified by their primary biochemical composition into carbohydrates, proteins, and fat for health and other dietary purposes. Vegetarians distinguish between "vegans," who eat no animal products, and "ovo-lacto-vegetarians," who eat eggs and milk products.

There are many informal and slang words for food in general: "chow," "grub," "mess," and "eats" are a few examples.

## Words for Meals

English has various names for the customary times of day when people eat. "Meal" is a general term that includes breakfast, lunch, and supper (or dinner). "Dinner" is the largest meal, which can be midday or evening, depending on the region and culture. "Supper" is an evening meal, but for many people in the United States, "supper" and "dinner" are synonyms. The *Longman Lexicon of Contemporary English* (p. 217) contrasts meal terms for the British middle class and working class, and for Scotland in general. British middle-class words are similar to American usage, with the addition of "(afternoon) tea." In Scotland and among the British working class, "dinner" is served at noon, tea is served around 4 P.M., "(high) tea" is a light cooked meal served between 5 and 6 P.M., while "supper" is a small meal between 9 and 10 P.M.

In contrast to "meal," the term "snack" refers to food eaten between meals. Fancy or elaborate meals, especially those served on special occasions, are termed "feasts" or "banquets."

For meals with several courses, the courses are generally named according to the order in which they are served. In English the first course is the "appetizer" (or "starter" or "hors d'oeuvre"), followed by the main course or "entrée," and finally the "dessert." Although many English culinary terms are taken from French, usually with the French meaning, the sense of "entrée" has undergone a slight semantic shift. Traditional formal French dinners typically consisted of five courses: the *hors d'oeuvre* (literally "out of the work," often a soup or pâté), then the *entrée*, usually fish, followed by the *plat principal* (or *plat de résistance*, *pièce de résistance*), then *fromage* (cheese), and finally *dessert*.

## Cooking Vocabulary

Preparing food by cooking is a universal practice in human societies, and every language has words to differentiate cooking methods. In English, "cook" is a general term with more specific words: "boil" (cook in water), "bake" (cook with dry heat in an enclosed space), "grill" or "broil" (cook over/under an open flame), "roast" (originally, cook on a spit over an open flame, but now partly synonymous with "bake"), and "fry" (cook in fat). English has highly specific words, including "steam," "poach" (cook gently in water), "deep-fry" or "French-fry" (submerge in hot oil), "sauté" or "pan-fry" (fry quickly in fat), or "stew" (cook slowly for a long time), "simmer" (gently boil), "braise" (sauté then simmer), and "barbecue." A relatively recent addition is "microwave."

Although German is closely related to English, the same concepts are expressed with somewhat fewer words. *Kochen* can mean "cook in general" or "boil" as a specific cooking method. *Braten* covers pan-frying, grilling, and

broiling, while *backen* is the general word for “bake.” Other words are *sieden* (boil, simmer), *rösten* (roast), and *grillen*, a specific term for grilling. *Dünsten*, *schmoren*, and *dämpfen* (braise, stew) are more specific.

Polish, like German, uses one word, *gotować*, for cooking in general and for boiling. Other words are *smażyc* (fry), *duścić* (stew), and *piec* (bake, roast).

In Japanese the general term for cooking is *nitaki* or *ryōori-suru* (prepare food). *Niru* is a general term for boiling, with two subterms: *yuderu* for boiling solid food and *taku* for boiling or steaming rice. *Musu* means ‘steam’. *Yaku* covers baking, roasting, broiling and frying, but there are specific words as well: *ageru* (deep-fry), *itameru* (stir-fry), *aburu* (grill or broil).

The general term for ‘cook’ in Mandarin Chinese is *shāo*. Its basic meaning is ‘burn’, and in context it can also be interpreted as ‘bake’, ‘roast’, or ‘boil’. Other cooking words are *zhǔ* (boil), *zhēng* (steam), *chǎo* (stir fry) and *jiān* (fry in a little oil), *zhà* (deep-fry), and *káo*, a general word which covers baking, roasting, and broiling. More specific words include *dùn* (stew in broth or sauce) and *mēn* (cook slowly in a covered pot).

Amharic, a Semitic language spoken in Ethiopia, uses the term *bessela* (cook), with specific words for cooking methods and type of food cooked: *fella* for boiling liquids, *k’ek’k’elle* for boiling solid food, *gagger* for baking bread, *t’ebbesse* for frying or roasting meat, and *k’olla* for parching grain.

In general, languages have a variety of different words for cooking methods based largely on whether water, oil, dry heat, or an open flame is used. There is almost always a specific word for “boil,” and often this is also the general word for “cook.” Grilling (broiling), baking, roasting, and frying can be denoted by different words, but frequently these are combined into one or two general words.

### Eating and Drinking Vocabulary

All languages have words for eating and drinking. In English, the distinction is whether solids or liquids are consumed. German, in addition to *trinken* (drink), contrasts *essen* (eating by humans) and *fressen* (eating by animals). Navajo has a general word for “eat,” and several specific ones whose use depends on the amount, shape, and consistency of the food eaten. (Corresponding distinctions occur in Navajo verbs for handling food, but not in verbs for cooking, which depend on the cooking method.)

English has two sets of specific verbs for eating. The first set comprises intransitive verbs for eating meals or amounts of food: these include “dine,” “lunch,” “snack,” and “nosh.” The second set comprises transitive verbs that describe the manner of eating or drinking: these include “gobble,” “munch,” “nibble,” “lick,” “guzzle,” “sip,” “wolf down,” and “slurp” (Fellbaum and Kegl, 1989).

### Words for Wine

Although we can perceive only four basic tastes—sweet, sour, bitter, and salty—we can perceive thousands of odors. These odors fall into a few basic categories: floral, ethereal, musky, resinous, foul, and acrid (Ackerman, p. 11). The sense of smell is extremely sensitive and selective. “Our olfactory threshold is about 6,000 to 10,000 times as sensitive as that for taste” (Amerine et al., 1959, p. 483). What we perceive as taste is really a combination of taste and smell.

A very large, creative vocabulary has been developed to describe the taste and smell of wines, and new words are continuously invented. The vocabulary includes scientific-technical terms mostly used by experts (for example, “malo-lactic fermentation,” “botrytis nose”), and widely used varietal names, like “Chardonnay” and “Pinot Noir.” Some words are descriptive: for example, wines can be “sweet” and “dry.” However, a large part of the vocabulary consists of words that have both a descriptive and evaluative component. A wine with a high acid content can be “tart,” if it is judged desirable, or “sour,” if undesirable. A wine’s “body,” a function of dissolved solids (tannin, acids, and fruit extracts) and alcohol, can be either “heavy” or “light,” words that are evaluatively neutral. “Rich” and “big” are positive terms for “heavy,” while “coarse” is negative. “Thin” and “watery” are negative terms for the neutral term “light.”

The purely descriptive and descriptive-evaluative words are usually divided into the following three categories: “Taste”—sweet or dry (residual sugar or no sugar), sour (acidic), and bitter (tannic); “bouquet and aroma”—the smell of the wine; and “texture”—the feel of the wine in the mouth. This last category of texture includes body, and also includes sensations such as prickliness from certain acids and astringency from tannin. Positive texture words include “smooth” and its synonyms “soft,” “silky,” “velvety.” Negative descriptors include “rough,” “hard,” and “harsh.”

The numerous descriptors for specific tastes and smells are based on a similarity to some fruits, vegetables, or other objects. Wines can be “fruity,” “vegetal,” or more specifically, have the taste or smell of any fruit (cherry, apple, melon), vegetable (green bean, asparagus, bell pepper), spice (cinnamon, nutmeg), or herb (thyme, peppermint). Wines can also be “meaty,” “yeasty,” “perfumed,” “flowery,” or “smoky.” These specific descriptors are nouns or adjectives derived from nouns.

Perhaps the most interesting, most discussed, and most ridiculed aspect of wine description is based on metaphor. “Body,” the weight of the wine, gives rise to an open set of semantic extensions. Since heavy things are usually big, various size words are used as synonyms: “huge,” “massive,” “mammoth.” Other metaphors based on the human body include “muscular,” “brawny,” “fat,” “fleshy,” “stout,” “beefy,” “big-boned,” and “chunky” for heavy wines, and “lean,” “sleek,” “sinewy,” “svelte,” and “thin” for light wines.

The “structure” of a wine is its solid components—“the combined effect of elements such as acidity, tannin, glycerin, alcohol and sugar as they related to a wine’s texture” (Steiman, p. 231). The concept of structure has generated terms like “backbone,” “frame,” and “framework.”

Especially interesting and creative are metaphors based on personality and character. Wines, whose properties are immediately apparent, can be “generous,” “approachable,” “assertive,” “bold,” “brash,” “loud,” “sassy,” “flamboyant,” or “in-your-face.” Wines with subtler properties are “shy,” “sly,” “reserved,” “reticent,” or “subtle.” Many terms based on human personality are mainly evaluative: “agile,” “charming,” “classy,” “diplomatic,” “friendly,” “graceful,” “polished,” “refined,” and “elegant” are positive, while “aggressive,” “stingy,” and “mean” are negative.

Some wine descriptors are based on age and the life cycle. “Young” and “old” are a function not only of when a wine was made but also of its stage of development from grape juice to drinkable wine to vinegar. Wines that are too young can be “immature,” “green,” “closed,” “dumb” (mute), “tight,” (tightly closed, tightly wound), or “locked in.” Wines at the peak of drinkability are “open,” “mature,” “ripe,” “developed,” “evolved,” or “mellow.” Wines that are too old can be described as “withered,” “dying,” “decrepit,” “over-the-hill,” or “senile.”

“Balance” is the way in which the various wine components interact. Positive descriptors include “balanced,” “harmonious,” “integrated,” “focused,” “formed,” “coordinated,” and “well-defined.” Negative words are “unbalanced,” “unharmonious,” “diffuse,” “disjointed,” “uncoordinated,” and “muddled.”

In the vocabulary of wine description, synonyms can be added for existing concepts. “Big” is a conventional word for full-bodied wines, and general mechanisms of semantic extension allow speakers to generate descriptors like “gigantic,” “towering,” or “elephantine” to express the same idea with greater rhetorical effect.

French, German, Italian, Spanish, and other languages spoken in wine-growing countries also have extensive wine vocabularies that cover scientific-technical, common descriptive, and evaluative meanings. Vocabularies for beer, coffee, and tea have many parallels, and even share many of the same words (for example, “rich,” “light,” “deep”).

**LAPPS.** The Sami (Lapps) are a native minority of northern Norway, Sweden, Finland, and the Kola Peninsula in Russia. Their territory was once much larger than it is today, especially in Finland. The Sami land is not homogeneous, but is divided into different ecological zones ranging from the coast of the Arctic Sea via the high mountains of Scandinavia to the northern forests. From a historical perspective, this territory supports various types of economies, with a focus on reindeer breeding, reindeer hunting, hunting combined with fishing in the sea and in lakes (in some regions combined with small farms), or pursuit of sea mammals. It is also important to connect the economy to different types of consumption with the emphasis on reindeer meat or milk, game and fish, and seal. Vegetables, berries such as cloudberries, bilberries, and lingonberries, and (infrequently) bread can also be seen as complements. Mercantile goods like flour, coffee, liquor, and horse meat, complete the picture.

The transition from hunters and fishers to reindeer herders began at different times in different parts of the widespread Sami territory. For example, the Sami practice of reindeer hunting combined with a nomadic lifestyle has existed in Sweden ever since the end of the Middle Ages.

The reindeer has long been the comprehensive symbol of Sami food culture, and today reindeer meat is exploited by restaurant culture of the Nordic countries, outside of the Sami territory. There one can find it on menus as roast reindeer (for example, under the name of *suovas*) or as small pieces of meat in a sauce with mashed potatoes and lingonberry (*renskav*).

Formerly the Sami used almost every part of the reindeer as food, including viscera, minced and cooked udder, hooves, and the brain (as an ingredient in bread). Reindeer cheese was once considered a delicacy, even as a commercial product, as were the tongue and heart. Reindeer milk could also be mixed with angelica and sorrel.

A Lapp herding reindeer on the tundra near Arrisovarre, Norway. © FARRELL GREHAN/CORBIS.

Samis traditionally boiled meat and fish. Dried fish (salmon and pike) were a replacement for bread and were also a trade commodity. In the nomadic society there was no oven in the Sami tent—the infrequently consumed bread was made of purchased barley (and later, wheat) on the hot hearth.

Breakfast was not a traditional Sami meal. In the nineteenth century it became a coffee meal or snack. Boiling meat and fish at noon and in the evening was the most common kind of traditional cooking. The principal meal was served in the evening. Traditionally, cooking in Sami culture was a male duty.

After the slaughtering of reindeer, a symbolic meal was traditionally served. This *renkok* (formerly and especially in gastronomic literature referred to as *lappkok*) consisted of marrowbone, liver, tongue, or heart boiled in a fat gravy. One can find such a meal at restaurants, especially in Lapland. Also, until the twentieth century, the Sami served a feast with boiled meat and a fat gravy after a successful bear hunt.

The money market has brought Western foodstuffs to the Sami food culture—at first as status food but gradually more and more as basic food—but at the same time, reindeer meat has retained its strong symbolic value for Sami identity.

**LAROUSSE GASTRONOMIQUE.** The chef Prosper Montagné's *Larousse gastronomique* was first published in France in 1938. Alongside Georges-Auguste Escoffier's *Le guide culinaire* and Louis Saulnier's *Le répertoire de la cuisine*, the *Larousse gastronomique* became one of the key reference works on French national and regional cuisine for the professional chef. The *Larousse gastronomique* is a reference text that codifies a history of the French culinary arts from the distant past to the present day in encyclopedic form. Entries cover such items as culinary terminology, foods, kitchen equipment, tech-

niques, national cuisines, regional French cuisines, and historically significant chefs and restaurants.

Montagné's work signaled a break with the preceding era of French cookery as exemplified by the architectural creations of Marie Antoine Carême. Montagné emphasized dishes that were simple by Carême's standards, and the shortened menus were delivered in the Russian style service—meals were served in courses on individual plates. This philosophy inspired the name of his culinary encyclopedia. Montagné covered the range from the relatively new haute cuisine to French provincial and home cooking with some attention to classic dishes of other nations.

Three editions of the *Larousse gastronomique* have been published in English. The first edition, published in 1961, was an Anglo-American venture edited by Charlotte Turgeon and Nina Froud. A fairly direct translation of the Montagné text, this edition included updated food science entries and English and American measurements. One translator is the noted British food writer Patience Gray and it concludes with an additional reading list compiled by Elizabeth David.

Jennifer Harvey Lang edited the English second edition, published in 1988, from the 1984 French edition compiled and directed by Robert J. Courtine. Courtine's introduction describes the first edition as a monumental work, albeit one in need of some refurbishment. These new editions take into account technical innovations, advancements in food science, and a new culture of dining characterized by simpler meals and a dietary palette expanded through travel and global commerce. Yet the core achievements of Montagné, including his recipes and technical advice on classical and regional French dishes, are preserved.

For the third English edition, published in 2001, Jennifer Harvey Lang worked from a new French edition edited by Joël Robuchon, the president of the Gastronomy committee of the Librairie Larousse. This edition claims to have retained the classic dishes and techniques of the original edition with a newfound sensitivity to global influences in technique, presentation, ingredients, and recipes. It is 1,350 pages, over 150 pages longer than the preceding English edition and it includes two hundred new recipes and four hundred new entries.

The *Larousse gastronomique* no longer sits alone—if it ever did—on the shelves of professional chefs. Although considered a classic reference text on classical French dishes, ingredients, and techniques, the contemporary chef has access to numerous books that cover the same ground. Furthermore, the third edition addresses some elements of a growing interest in fusion cuisine and the cuisines of other nations, but it cannot provide the detail of more specialized cookbooks. Nevertheless, it covers an immense breadth of culinary material, justifying its continued importance.

**LAST SUPPER, THE.** The final meal of Jesus with his followers in Jerusalem the evening before his crucifixion on the orders of Pilate in or around 30 C.E. is called the Last Supper. During the meal Jesus is said to have expressed a desire to be remembered by breaking bread and sharing a cup of wine, inspiring the central ritual of Christianity variously called the Eucharist, Mass, Lord's Supper, or Holy Communion. Leonardo da Vinci's fresco, executed in Milan in the 1490s, is probably the best-known pictorial representation of the Last Supper.

The participants left no firsthand reports of the Last Supper. Instead, varying accounts were handed down and recorded two or more decades afterward in books eventually collected into the New Testament (Matt. 26:17–30, Mark 14:12–25, Luke 22:7–38, John 13–17, and 1 Cor. 11:23–29). These and noncanonical sources, notably *Didache* 10 and 9 (in presumed chronological order), are the origin of a variety of liturgies, including washing one another's feet (John 13:14), so the details are open to conjecture.

Throughout his mission Jesus shared meals so enthusiastically that he was accused of being a glutton and a drunkard (Luke 7:33–34; Matt. 11:18–19). Thus it is plausible that he would have told companions to seek out an upper room in a house, where he organized supper before being seized by Roman authorities.

In the eastern Mediterranean the standard beverage, staple, and accompaniment were wine or water, bread, and a range of relishes, including fish. These all featured in both Jesus' reported sharing (such as the mass distribution of loaves and fishes) and early versions of the subsequent Christian agapes (love feasts) and Eucharists (thanksgivings).

Any familiar religious shape to the last meal would have been Jewish, since Jesus did not seem to have intended to inaugurate another religion. In that context the presence of women might have been quickly ignored in favor of twelve male disciples representing the twelve

The Last Supper is a recurring image in Christian art. This scene is a detail from the tympanum of the late-thirteenth-century cathedral at Strasbourg, France.

tribes of Israel. Some sources associate the Last Supper with Passover, the Jewish holiday of unleavened bread and spring lamb, which presumably would have taken the group to Jerusalem and which subsequently provided the timing of Easter, along with the symbol of Jesus' own sacrifice.

His followers soon believed that Jesus used distinctive words of institution over the bread and cup. These might have emerged from Passover procedures, as argued by Joachim Jeremias in *The Eucharistic Words of Jesus* (1966), and Jesus would surely have employed some form of Jewish thanksgiving or *berakah* standardly used as a grace before food. Yet Dennis E. Smith and Hal Taussig, in *Many Tables* (1990), argue for a Greco-Roman setting for the meal or more plausibly for early interpretations, so the bread and cup derive from the formal *deipnon* or dinner and subsequent *symposion* or talking over a shared drinking cup.

In Paul's influential version, probably written in 53–54 C.E., the key points are that Jesus took a loaf of bread, gave thanks, broke it, and said: "This is my body which is given for you. Do this in remembrance of me." After supper Jesus said: "This cup is the new covenant in my blood. Do this, as often you drink it, in remembrance of me" (1 Cor. 11:23–25). Accredited priests then trans-

formed the bread and cup into Jesus' actual flesh and blood, and this transubstantiation was added to the matters for rancor and division. Some Protestants even retreated so far as to commemorate a self-proclaimed eater, drinker, and server entirely without bread or wine.

**LA VARENNE.** Little is known about the life of François Pierre (1618–1678), who signed with the name La Varenne. One account states that he was born in the Burgundian town of Chalon-sur-Saône and died in Di-

jon in 1678, and we know that from approximately 1640 to 1650 he worked in the kitchens of the Marquis d'Uxelles. His fame is due to the publication, in 1651, of *Le Cuisinier françois* (The French cook), the first of a new generation of cookbooks to document the changes that had taken place in French cuisine during the first half of the seventeenth century, and by far the most popular. Cooks were abandoning the use of spices that typified medieval and Renaissance cookery and replacing them with native European herbs: parsley, thyme, bay leaf, basil, etc. Many recipes, which are still popular with French chefs today—*bisque* and various *ragoûts*, for instance—are mentioned for the first time in *Le Cuisinier François*. La Varenne emphasizes the use of the *roux*, almost systematically employs a *bouquet garni* (a bundle of herbs) in stews and soups, and is the first to publish a recipe for *Oeufs à la neige* (snow eggs). His was also the first French cookbook to be translated into English (1653).

Although some have attributed other works to La Varenne, most notably *Le Pâtissier françois* (The French pastry chef) and *Le Confiturier françois* (The French confectioner), recent scholarship has shown that there is little reason to believe that he is the author of these texts.

**LEAF VEGETABLES.** Leaf vegetables are a diverse and eclectic group of plants comprising several different taxonomic plant families: Aizoaceae, Amaranthaceae, Asteraceae (Compositae), Basellaceae, Boraginaceae, Brassicaceae (Cruciferae), Chenopodiaceae, Convolvulaceae, Cucurbitaceae, Euphorbiaceae, Malvaceae, Phytolaccaceae, Polygonaceae, Portulacaceae, and Tetragnoniaceae. In the literature, leaf vegetables are commonly known as “greens” and “potherbs.” They are grown for their tender, succulent, and normally green leaves, and are usually cooked before eating, thus the name “potherb.” Alternatively, the salad greens, for example, lettuce, radicchio, and endive, are usually eaten uncooked. Nevertheless, the leaf vegetables can be added fresh to tossed salads, giving the salad color and novel flavors. Not included in the group are those plants with leaves that serve as an important herb or flavoring ingredient, but do not constitute the main ingredient in the dish, such as cilantro, parsley, rosemary, etc.

Additionally, there are a large number of plants the leaves of which are eaten in certain parts of the world although the leaves are actually a secondary crop. For example, in Southeast Asia, chili pepper (*capsicum*) leaves are eaten, but it is the fruit that Americans usually consume. Other examples of plants whose fruits or roots are the primary crop but whose leaves are also consumed are peas and beans, plantain, cassava, cucumber, radish, and sweet potato.

Leaf vegetables may be cool-season or warm-season crops and can be grown as annuals or as perennials. In addition, some leaf vegetables are adapted to the tropics, while others are adapted to the temperate climates. Depending on location, leaf vegetables are either a main crop or treated as a minor crop. The more important leaf vegetables, based on dollar value, are spinach, kale, collards, mustard greens, and Swiss chard. Other leaf vegetables such as New Zealand spinach and dandelion are popular with home gardeners and are grown on a limited scale by market gardeners.

Leaf vegetables are among the most nutritious vegetables on a fresh weight basis and are also among the world's most productive plants in terms of nutritional value per unit area, in part because they grow rapidly, allowing several crops or harvests in a season. Although some of the constituents are lost during cooking, they still contribute significant amounts of provitamins A and C and several minerals. Leafy vegetables are also good for the eyes. Age-related macular degeneration is a leading cause of blindness among individuals over the age of 50. A research study in Massachusetts found that people who ate spinach, collards, and other dark green, leafy vegetables five or six times a week had about a 43 percent lower risk of the disease than those who ate it less than once a month. The typical shelf life for most leaf vegetables is ten to fourteen days.

#### Major Leaf Vegetables

**Spinach.** Spinach (*Spinacia oleracea* var. *inermis*) is a member of the Chenopodiaceae family, which also includes table beet, Swiss chard, sugar beet, and amaranth. Spinach is native to an area near present-day Iran and was first cultivated by the Persians more than 2,000 years ago. Records of its use are meager, but it is believed that cultivation of the crop developed during the period of the Greek and Roman civilizations. It was introduced to China in 647 C.E. and apparently was transported across North Africa to Spain by the Moors by 1100. Two seed types exist, one having a smooth, round shape and the other an irregular, prickly shape. The crop was known in Germany in the thirteenth century only in the prickly-seeded form. Smooth-seeded spinach, which is used exclusively in today's commercial production, was not described until 1552. The colonists introduced spinach to the Western Hemisphere, and it was listed in American seed catalogs by 1806.

## SPINACH

Apparently the time of the introduction of spinach into China is well-recorded in Tang Dynasty history (618–907 C.E.) because it marked the flow of many new food offerings of grain and seed from Tibet. Also, the trade routes to the West went through Tibet, and presumably spinach may have been traded from its origins in Persia. One story is that it was included as a part of the bridal offerings that were carried into China with the marriage of Princess Wencheng to the Tang Emperor Taizong sometime before 641 C.E. This marriage was well recorded in both Han and Tibetan writings and folklore. It is also known that during this same period many other food products flowed (such as pepper and cardamom) into China. This trade resulted from the extensive connections Emperor Taizong had established with the western Asian region. While it is possible that spinach came into China through the marriage, it was also likely that it could have come anytime during the later reign of this emperor after establishing all of these connections. It is also relevant to note that this period (618–641 C.E.) also marks the time when both tea and porcelain were first extensively traded with the west.

*Solomon H. Katz*

Spinach is the most important leaf vegetable in the United States. The edible portion of the plant is the compact rosette of fleshy leaves attached to a short stem. Leaves vary from ovate or nearly triangular to long and narrow arrowhead shapes; the latter are a characteristic of more primitive types. Leaf margins may be smooth or wavy, and surfaces are smooth, semisavoyed to heavily savoyed (crinkled). The crinkled appearance of the savoy tissue results from differential growth of parenchyma tissues between leaf veins.

When plants have attained marketable size, which, depending on the season, can be 30 to 80 days, and when overwintered as much as 150 days, they are pulled or undercut below the stem. Each plant will have five to eight fully developed leaves. Intact plants are trimmed, and several are tied together in bunches and packaged. Not all hand-cut spinach is bunched. Some are bulked into harvest baskets and sold in that manner. Savoy types are preferred for the fresh market because the leaves are dark green and resist compression during packing, thus allowing for better aeration, cooling, and postharvest life. Most of the commercial frozen spinach is machine-harvested. The machines have cutting blades adjusted to cut

four to six inches above ground level to reduce the amount of petioles harvested with the leaves. The smooth or semisavoyed leaf types are generally used for machine harvesting because they yield more and are easier to clean. A limited amount of greenhouse spinach is produced in northern Europe during the winter.

Because spinach has a high leaf-surface area and a high respiration rate, it must be cooled rapidly to prevent weight loss and decay. Overheating will destroy quality. Thus, rapid cooling is essential to reduce wilting and weight loss. Vacuum cooling can give satisfactory cooling within ten minutes, usually applied after bulk packing and washing. Hydrocooling (cold water application) takes longer than vacuum cooling but is more feasible for small market operations. Following hydrocooling, excess water must be removed by centrifuging; otherwise postharvest diseases begin to develop. The product can then be stored under shaved ice to preserve freshness.

A serving (1½ cups) of cooked spinach has forty calories and provides 70 percent of the recommended daily allowance (RDA) for adults of vitamin A, 25 percent of the RDA of vitamin C, and 20 percent of the RDA of iron (see Table 1). Spinach also contains high levels of calcium, phosphorus, and potassium. It has moderate levels of protein. However, not all constituents of spinach are nutritionally beneficial. Oxalic acid in spinach reacts with calcium to form calcium oxalates. Excessive oxalic acid may interfere with calcium absorption in humans, a condition particularly serious for infants. Levels of oxalic acid are substantial in all spinach cultivars, although apparently less in savoy types than in smooth leaf types. Oxalic acid is also found in many of the other leaf vegetables, including chard and, especially, rhubarb. The leaves of rhubarb are toxic and should never be consumed. The stalks should be fresh when eaten.

An additional problem relates to the accumulation of nitrogen in the nitrate form, especially in spinach fertilized heavily with ammonium nitrate and grown under high temperatures and low light intensity. Nitrates convert to nitrites in digestion, and nitrites will oxidize hemoglobin to form methemoglobin. This substance can lead to methemoglobinemia, a disorder of humans and ruminants. Nitrates can also form carcinogenic nitrosamines. These toxic constituents in spinach do not present a risk when the crop is grown with proper fertilization and is consumed as part of a balanced diet.

**Swiss Chard.** Swiss chard (*Beta vulgaris* var. *cicla*) is a type of beet developed for its large crisp leaves and fleshy leafstalks rather than for its roots. Early civilizations utilized the roots as a medicine. The first records of cultivation indicate that the Eastern Mediterranean region, not Switzerland, was the place of origin. Aristotle wrote of seeing a red chard in 350 B.C.E. From this leaf plant was selected the swollen root form, the table beet. Although large acreages are not common, it is grown widely to supply local markets.

Swiss chard leaves are of best quality just when fully expanded or slightly earlier but remain succulent throughout the season as long as the leaves are harvested at the proper size. The succulent, glossy, dark green leaves are usually slightly crinkled or savoyed. Sometimes the fleshy white leaf midribs are separated from the leaf blade and prepared much like celery or asparagus. The midrib color can be white, red, yellow, pink, or green. Swiss chard is prepared for the market by washing thoroughly, grading, and bunching. Storage is not recommended, but it can be kept for short periods.

A serving of Swiss chard (3½ oz.) provides 130 percent of the adult RDA of vitamin A and 25 percent of the adult RDA of vitamin C (see Table 1). Like spinach, which is related, Swiss chard has high levels of oxalates.

**Kale and Collards.** Members of the Cruciferae family, kale and collards (both *Brassica oleracea* var. *acephala*) are known as “greens” and “soul food” in the southern United States, where they are most popular. Unlike cabbage (*Brassica oleracea* var. *capitata*), neither kale nor collards forms a head—thus the name “acephala” which means ‘forming no head’. Kale and collards are the oldest forms of cabbage and are native to the eastern Mediterranean region of Europe or to Asia Minor. The use of kale as a food dates to 2000 B.C.E. or earlier. The Greek philosopher Theophrastus described a savoyed form of kale in 350 B.C.E. Traders and nomads introduced these leaf vegetables to other parts of the world, and they were introduced to the United States from Europe in the seventeenth century.

Both kale and collards have dark green leaves that form a rosette-like whorl toward the apex of erect unbranched stems. Even though collards and kale belong to the same taxonomic group, they are quite distinct. Collards differ from kale mainly in leaf shape and flavor. Collards have large, broad, flat, smooth leaves with smooth leaf margins; kale has a greater variability of leaf types. Most kales have largely upright heavily curled leaves. The decorative leaves of kale have given rise to its use as an ornamental plant. Flowering kale is very attractive for landscape plantings and is edible though not very palatable. The term “flowering” derives from the shape and coloration of the plant, which resembles a flower, and does not refer to actual flowers.

Kale is also called borecole (“winter cabbage”). The name “collard” is a corruption of *colewort* or *colewyr*, Anglo-Saxon terms meaning young cabbage plants. Curly leaf forms of kale occur because of disproportionate growth along leaf margins, whereas the savoy (crinkled) appearance is due to nonuniform growth of portions of the leaf laminae. Kales and collards are the hardiest of the cole corps; when properly acclimated, they can tolerate temperatures to 0°F or lower and they are often overwintered. In addition, kale and collards have good tolerance to high temperatures (80° to 85°F), although growth stops at about 85°F. However, the best-quality

kale collards are grown in the cooler part of the year. In general, collards are more heat tolerant, while kale is better adapted to cooler weather.

Both kale and collards are biennial, meaning that they will flower after an extended exposure to cold weather. A vigorous collard plant may reach a height of three to four feet. Kale is somewhat smaller. Two general types of kale are grown for the market: curly leaf (the most widely grown) and smooth leaf. Of the curly leaf forms, Scotch kale is rather light green, with very ruffled, finely divided leaves; it may be dwarf or tall, with the dwarf form preferred. Because of the curly leaves, one of the commercial production problems is removing sand from the leaves.

Collards can be harvested by cutting young plants. Large plants can be cut off, or the lower leaves can be removed during the season. Leaves of both crops should be young and tender. The flavor of kale is sweeter after a frost, and many prefer to harvest at that time. After harvest, the leaves or small plants should be washed, graded, and bunched or packed. Shipments are made with an ice covering to preserve freshness. When necessary, kale and collards can be stored for ten to fourteen days at 32°F at 90 to 95 percent relative humidity.

Both kale and collards excel in food value, with kale superior to most vegetables in protein, vitamin, and mineral content. On a fresh weight basis, kale is among our most nutritious vegetables. One serving (3½ oz.) provides 200 percent of the adult RDA of vitamins A and C and 13 percent of the calcium RDA for adults.

Siberian kale (*Brassica napus*) has other common names such as Hanover kale, Hanover salad, spring kale, and Hanover turnip. It is a cool-season crop that belongs to the Brassicaceae family. Siberian kale cultivars vary considerably in appearance. The plant might best be described as resembling the ordinary collard, but it is not as curly as kale. The leaves form a rosette, and are usually smooth like collards rather than hairy like turnip leaves. The petioles vary from purple to white. Although it is sometimes compared to the turnip in growth habits, it does not form a fleshy root like turnips. Young tender leaves are used in cooking.

**Amaranth.** Within the genus *Amaranthus*, more than fifty species, including both cultivated and weedy species, are eaten as greens. The cultivated species are collectively called “amaranth.” Another crop of the amaranth family grown in tropical Asia for its edible leaves is *Celosia argentea*. In Southeast Asia, the many cultivars of this species are usually classified by leaf color and shape. Common names for *Amaranthus* include bush greens, Chinese spinach, hon-toi-moi, pigweed, and tampala. Because of the large number of species used, there is considerable variability in growth habit, leaf shape, color, inflorescence characteristics, and utilization. Leaf shape and color also vary considerably among the different seed accessions. Some are red, others are green, while others

TABLE 1

## Nutritional constituents of leaf vegetables

Crop	Water (%)	Energy (cal)	Protein (g)	Fat (g)	Carbo-hydrate (g)	A (IU)	C (mg)	Thiamin (mg)	Ribo-flavin (mg)	Vitamins

## AMARANTH

Amaranth is one of the most ancient crops of the Aztecs of Mexico, who domesticated it about 5000 B.C.E.; it appears to have been independently domesticated also among the Inca of Peru. Among the Aztecs amaranth was cultivated first in the *chinampa* system; fertile algae-rich mud from their garden canals was made into seed beds, and the amaranth was allowed to grow to about eight to ten inches in height and was then transplanted to fields in the higher ground, where it was usually intercropped with maize. After the Spanish conquest, the continued use of amaranth was prohibited because the red color of the seeds reminded the Spanish of blood and its connection to traditional Aztec religious practices.

Solomon H. Katz

may be variegated, usually with purplish patterns on a green background. Major leaf vegetable amaranth species are *Amaranthus tricolor*, *A. lividus*, *A. dubius*, *A. gangeticus*, *A. blitum*, and *A. hybridus*. *A. spinosus*, known as uray, is a vegetable of some importance in the Philippines. Amaranth is grown not only as a leaf vegetable, but as a grain (*A. caudatus*) in subtropical and tropical climates of Africa.

The green-leafed variety of vegetable amaranth (*A. tricolor*) has been offered in the United States as the cultivar *tampala*. It is as acceptable as spinach when cooked, but not raw. *A. lividus*, known as bondué, is grown for vegetable uses in tropical Africa. Young plants of *A. leucocarpus* are a leaf vegetable in Algeria; in addition, the seed is made into candy. The green form of *A. gangeticus*, Chinese spinach, is most commonly cultivated for use as boiled greens in Asia.

For many of the leaf vegetable *Amaranthus* species, centers of diversity are Central and South America, India, and Southeast Asia, with secondary domestication in western and eastern Africa. The greatest diversity of leaf amaranths is found in India. The leaf amaranths are popular, low-cost, and a good protein source for the populations of many tropical, subtropical, and temperate regions.

Most leaf-type amaranth plants are erect, about one foot to three feet high, and produce numerous small flowers on terminal and axillary spikes. When harvested, plants are pulled with the roots left on to facilitate bunching. In another method, partial leaf removal is made with regrowth permitted for successive harvesting. Frequent harvesting, every seven to ten days, tends to delay flowering and encourage new shoot and leaf growth. Postharvest life is relatively short because of rapid wilting of the tender foliage.

Some general disadvantages of amaranths are the early, short-day flowering response and low-temperature sensitivity of some species and the high calcium oxalate content in leaf tissues. Nevertheless, these plants supply large amounts of provitamin A, vitamin C, protein, and fiber. Amaranth is not as high in vitamin A as spinach, but other constituents are comparable.

**Mustard Greens.** Mustard is often used in a generic sense to identify somewhat morphologically similar brassicas even though they are different species. All belong to the Crucifer family and are native to Central Asia and the Himalayas. For instance, black mustard (*Brassica nigra*), white mustard (*Sinapis alba*), and Ethiopian mustard (*B. carinata* and *B. juncea*) are all called mustard greens. However, in the United States “mustard greens” normally refers to *Brassica juncea* var. *crispifolia*. When *Brassica juncea* seeds are ground, they produce the famous Dijon mustard. Mustard greens are strong flavored and pungent although the inner leaves are relatively mild and quite suitable for raw salad use. It is an annual cool-season plant with its early growth in a basal rosette. Leaf

form can vary among cultivars. Some cultivars have large leaves while others have leaves that are broad toward the apex. Within both forms are cultivars with curled or smooth leaf margins. The young tender leaves are harvested approximately seven weeks after sowing when they reach six to eight inches in height and before they become tough and woody. Plants are cut by hand, washed, and packed. They are packed for transit in the same way as spinach.

### Minor Leaf Vegetables

Several leaf vegetables are grown to a very limited extent on commercial acreage to meet a small but steady demand. One may find these leaf vegetables growing more frequently in home gardens. Some of these crops are normally thought of as weeds; however, they are grown because they feature some prominent characteristic that is favored among specific ethnic groups. These crops include broccoli raab, chaya, dandelion, garland chrysanthemum, garden sorrel, ice plant, kangkong, Malabar spinach, New Zealand spinach, orach, pokeweed, and purslane.

Broccoli raab (*Brassica campestris*) is also known by such names as raab, rapa, rapini, broccoli turnip, spring broccoli, cima di rapa, taitcat, Italian turnip, and Italian mustard. It is a highly regarded leaf green in Italy and other Mediterranean countries. The plant resembles turnip tops and sprouting broccoli but develops a much smaller, less compact inflorescence. The leaves are cut with the seed stalks before the flower buds open. There are two forms of broccoli raab: rapine, or spring raab, and rappone, or fall raab. Other than the season of maturity, there is no difference in appearance or flavor.

Leaf vegetables are ideal for greenhouse horticulture since many species can be forced during the winter months for early spring harvest. Angelo Favoretto, a Vineland, New Jersey, wine maker, supplements his income from grapes with an early crop of dandelion greens, a leaf vegetable rich in vitamins and minerals. © BOB KRIST/CORBIS.

Both go to seed very rapidly. In areas with a moderate climate, raab may be planted in the fall and overwintered to produce an early spring crop. Rappone seems superior to rapine for these fall plantings. In most areas, both are spring planted for early or late summer harvest. The harvest system is similar to that used for collards and turnips; the leaves and the flower stalks are tied together and sold as bunches. Raab is very perishable and must be marketed immediately.

Chaya (*Cnidoscolus chayamansa*) is a little-known leaf vegetable of dry regions of the tropics. The leaves are used as a green vegetable in many Latin American countries. The name “chaya” comes from the Mayan word for the plant, *ixchay* or *chay*. Other common names are tree spinach, chaya col, kikilchay, and chaykeken. Chaya is a large leafy shrub reaching a height of about six to eight feet. It somewhat resembles a vigorous hibiscus or cassava plant. The dark green leaves resemble okra leaves. The domesticated cultivars have little to none of the offending features—stem spines and leaf hairs—found in wild chaya. It is reported that “pig chaya” is one of the very best eating varieties. Plants are continuously harvested. Large leaves are cut into manageable pieces before cooking. Chaya is a good source of protein, vitamins, calcium, and iron. However, raw chaya leaves are highly toxic because they contain hydrocyanic glucosides. One minute of boiling destroys most of the glucosides.

Dandelion (*Taraxacum officinale*) has been encountered by almost everyone as a weed in lawns and gardens. However, there are cultivated varieties of dandelion that make excellent cooking greens. The dandelion is a European native with low-spreading deeply notched leaves forming a rosette pattern as they emerge from a central tap root. The varieties used as a leaf vegetable have been selected for their leafiness and freedom from bitterness.

The three major cultivars are Thick Leaf, Improved Thick Leaf, and Arlington Thick Leaf. The leaves are an excellent source of provitamin A, vitamin C, calcium, and several other minerals. Given that the plant is a perennial, the leaves are harvested by cutting below the whorl to keep the plant intact. The leaves are then washed, graded, and cooled.

Garland Chrysanthemum (*Chrysanthemum coronarium*) is also called edible chrysanthemum, chop suey greens, *shungiku* in Japan, and *tong bao cai* in China. It looks very much like a leaf version of the flowering ornamental chrysanthemum. A native of the Mediterranean region, it was introduced to Asia via contact with European traders. It is now a popular cooked green in Korea, Japan, and China. Leaf shape varies from lobed to highly indented. Daisy-like flower heads are yellow or yellowish white and are also eaten. All plant parts have aromatic flavor qualities, becoming most pronounced in older foliage.

Garden sorrel (*Rumex acetosa*) is a perennial plant that is closely related to rhubarb and buckwheat and is sometimes referred to as dock. However, the term “dock” has been used in Great Britain to include all members of the family Polygonaceae. Owing to its tart flavor, it is sometimes called sour dock and sour grass. In fact, sorrel derives from the Old French *surele*, meaning ‘sour’. Garden sorrel is of Eurasian origin with long, thin light green or reddish green, slightly crinkled, arrow-shaped leaves. Other *Rumex* species similar to garden sorrel are French sorrel (*R. scutatus*), spinach rhubarb (*R. abyssinicus*), patience dock (*R. patientia*), and Indian sorrel (*R. vescaarius*). French sorrel differs in being a short plant with branched stems that exhibit a semireclining growth habit. Leaves are arrow- or fiddle-shaped, more succulent, and smaller than garden sorrel. French sorrel is used like garden sorrel but has a milder taste. Spinach rhubarb is eaten like spinach, and the petioles are like rhubarb. Patience dock looks similar to garden sorrel although the plant is stouter and taller and has larger leaves and a noticeably stronger taproot than garden sorrel.

Ice plant (*Mesembryanthemum crystallinum*) is a little-known vegetable of the southern hemisphere. Ice plant is so named because of the shimmering silvery dots that cover the leaves. It has also been called fig marigold, frost plant, diamond plant, midday flower, and dew plant. This is not to be confused with New Zealand spinach, which is sometimes referred to in gardening books as New Zealand ice plants. Ice plant is a perennial that does best in hot, dry climates. It is grown as an annual when used as a green vegetable. The leaves are picked as wanted once the plant has several leaves and is well-established. The slightly acidic, fleshy leaves are boiled and served like spinach.

Malabar spinach (*Basella alba* & *B. rubra*) is also known as Ceylon spinach, climbing spinach, gui, acelga trepadora, bretana, libato, vine spinach, Indian spinach, and Malabar nightshade. The red leaf form belongs to

the *rubra* species, while the green form is classified in the *alba* species. *Basella alba* has an African or Southeast Asian origin, while *Basella rubra* is thought to have originated in India or Indonesia. Malabar is not a true spinach, but its leaves, which form on a vine, resemble spinach and are used in the same way. Malabar spinach can be grown from seeds or cuttings. The vine is normally trellised. Two vines are sufficient to supply a small family all summer and fall. The thick, fleshy leaves are cut off together with some length of the stem to keep the plant pruned to a desired shape. When cooked, Malabar spinach is not as slick in texture as many greens such as spinach. The Bengalis cook it with chopped onions, spicy chilis, and a little mustard oil. The mucilaginous texture is especially useful as a thickener in soups and stews.

Mizuna (*Brassica juncea* var. *japonica*) is an Oriental cooking green also known as potherb mustard, kyona, Japanese greens, and sometimes California peppergrass. It is widely grown in Japan but is found only occasionally in gardens in the United States. Mizuna is twelve to eighteen inches tall with yellow-green leaves that are smooth and a bit fuzzy, similar to curly mustard, but with a different leaf shape. Leaves of mizuna are deeply notched, narrow, feathery, and quite attractive. A single plant may have as many as 180 leaves clustered together in a compact, twelve-inch diameter bunch. It withstands frost and light freezes and is not quick to seed even in periods of warm weather that occur during the winter months. Leaves are ready for use any time after three weeks of growth. Leaves are removed as needed, keeping enough young foliage to continue the regrowth.

New Zealand spinach (*Tetragonia expansa*) is indigenous to New Zealand and became widely cultivated after it was introduced to Europe. It was introduced to England by Captain Cook in 1771 and was used on his voyages as a source of vitamin C. Presently, little is grown commercially in the United States, but it is popular with many home gardeners. Not a true spinach, it does somewhat resemble spinach in appearance and is used similarly. The plant is large, growing to a height of two or more feet in a spreading and branching habit of growth, and has thick succulent leaves. The young tops are harvested for boiling, and each harvest encourages new branching. Unlike many of the leaf vegetables, New Zealand spinach is a warm-season crop with very wide adaptation. It is an excellent source of fresh greens throughout the summer and is also frost-sensitive. Its flavor is comparable to that of spinach, but milder and without the astringency. In its early growth, New Zealand spinach is entirely vegetative. As it begins to develop, however, it soon produces flowers from the leaf axils. The flowers are considered undesirable for the market. Like spinach, tissues contain oxalates that render calcium nutritionally unavailable.

Orach (*Atriplex hortensis*) is a hardy branching monoecious annual of the Chenopodiaceae family that is a substitute for spinach. It is also commonly known as

mountain spinach, French spinach, and sea purslane. Some variations of the name are orache, arache, and orage. The name derives from the Old French *arrache*, a corruption of the Vulgar Latin *atripica*, from Latin *atriplex*; these in turn were from the Greek word for orach, *atrappaxus*. It is sometimes called salt bush because of its tolerance of alkaline soils. The plants have a tolerance to drought and salinity and are adapted to a broad temperature range. Orach is considered to have originated in northern India and has been used as a medicinal and food plant for more than 2,000 years, making it one of the oldest cultivated plants. It was widely grown until the eighteenth century but is of little commercial importance today although it is returning in popularity as an ingredient in mesclun salads. It is grown as a substitute for spinach in Europe and in the northern plains of the United States. It is seldom seen in the tropics. Its leaves are slightly crimped, soft, and pliable and are shaped like arrows that are four to five inches long and two to three inches wide. Plants can attain a height of five to six feet. A rosette of leaves first develops, followed by a seed stalk that can grow to a height of six to nine feet. There are four common varieties of orach. White orach is most often grown because it is the most tender and best flavored. The leaves are very pale green, almost yellow. Red orach has dark-red stems and leaves. Green orach, also called Lee's Giant orach, is very vigorous, with a stout, angular, branching stem. The leaves are rounder, less toothed, and darker green than those of the other varieties. The fourth is a copper-colored variety that is now much sought after by specialty growers.

Orach is a cool-season vegetable and is grown much like garden spinach. It is quick to bolt in summer. Although stems quickly elongate, flowering is slow, and plants tolerate growing temperatures too high for spinach. Young leaves may be harvested and the plants will continue growing for multiple harvests. Orach has a mild flavor much like that of spinach, but it contains less oxalic acid. Even when the plant goes to seed, young leaves are usable. However, old leaves are not palatable and are not harvested.

Pokeweed (*Phytolacca americana*) is a native plant throughout eastern North America. Other common names are inkberry, pigeon berry, coakun, pocan bush, scoke, garget, and poke salad. The branches bear clusters of flowers and dark red fruits that resemble the berries of a nightshade; pokeweed is therefore sometimes called American nightshade. It is a large-rooted perennial with a strong-growing tip, reaching up to ten or more feet in height. The top dies down in cold weather. There is little cultivation of pokeweed in the United States or elsewhere because it is gathered from the wild. All plant parts are poisonous. The young tender shoots and the older leaves may be eaten if boiled. The bitterness, and by association the poisonous compound, is removed by boiling and pouring off the cooking water until all the bitterness is removed.

## PURSLANE

Purslane has very high levels of the linoleic omega 3 fatty acid, which is essential and relatively low in the U.S. diet as compared with the higher levels of the omega 6 fatty acids. This imbalance of the ratio between the two classes of fatty acids may be the basis of an important nutritional imbalance.

*Solomon H. Katz*

Purslane (*Portulaca oleracea*) is known by various names such as kitchen purslane, garden purslane, and in Spanish, *verdolaga*. One of the more descriptive names for this plant is in Malawi, where it translates to “the buttocks of the wife of a chief,” because of the shape of the leaf. The exact origin of purslane is not known, but it is reported to have been used more than 2,000 years ago in Iran or India. Purslane is a popular vegetable in France, several other European countries, and Africa, especially in Egypt and Sudan. It was introduced to the United States from Europe. The name “purslane” derives through Old French *porcelaine* from Pliny’s Latin *porcilaca*. The cultivated forms are upright and more vigorous than the weedy form. It is a summer annual with small, oval, juicy leaves clustered at the ends of smooth, purplish-red, prostrate stems that arise from a single taproot. The leaves are usually stripped from the stems and are prepared like spinach. The taste is a cross between watercress and spinach. An undesirable quality of purslane is that its foliage, like that of spinach, contains oxalic acid and tends to accumulate nitrates.

Water spinach (*Ipomoea aquatica*), also known as kangkong, water glorybind, water spinach, water convolvulus, and swamp cabbage, is an important green leaf vegetable in Southeast Asia, Taiwan, Ceylon, and Malaysia. It is speculated to have originated in India but is now widely grown throughout the tropics. Water spinach can become an undesirable weed. The Florida Department of Natural Resources must issue a special permit to anyone wanting to grow it in Florida. There are two major forms (cultivars) that are cultivated in two ways, either upland (dry) or swamp (wet). Ching Quat, an upland variety, has narrow leaves, while Pak Quat, a swamp variety, has arrowhead-shaped leaves. The plants produce a trailing hollow vine that is adapted to floating in aquatic environments. The leaves are light green and look somewhat like sweet potato leaves. The upland types are started from seed or cuttings and are grown on trellises. Plants are often grown in nursery beds for transplanting later to the garden. Taking cuttings from plants

in the nursery beds is the usual method. Harvest may start six weeks after planting. The swamp types are usually planted with twelve-inch-long cuttings planted in mud and kept moist. As the vines grow, the area is flooded to a depth of six inches, and a continuous flow of water is maintained through the field, similar to the way watercress is grown. Harvest begins four weeks after planting. When the succulent tips of the vines are removed, lateral and upright branches are encouraged. These branches are harvested every seven to ten days. All parts of the young plants are eaten. The crop is fragile and requires rapid and careful handling to minimize damage and wilting. It is eaten like cooked spinach. A canned product is often available in ethnic markets.

## Conclusions

Leafy vegetables are consumed in most cultures and regions of the world. They consist of a wide range of different plants, yet no matter which leaf vegetable is used, it is usually prepared like spinach. The leafy vegetables contribute significantly to a nutritious diet. As a food source, the leafy vegetables are some of the best sources of provitamin A and vitamin C and supply good amounts of iron, folate, and other essential minerals. They are also an excellent source of phytochemicals, which aid in fighting heart disease and cancer.

**LEGUMES.** Legumes are members of a family of flowering plants known as Leguminosae. It is one of the three largest families of flowering plants, with approximately 690 genera and about 18,000 species. Legumes are a significant component of nearly all terrestrial biomes on all continents except Antarctica. Some are fresh water aquatics, but no truly marine species exist. The species within the family range from dwarf herbs among arctic and alpine vegetation to massive trees in tropical forests.

The leaves usually occur alternately on the stem and are compound, meaning each leaf is divided into separate leaflets. Both pinnate and trifoliate leaves exist. Legumes are easily recognized by the structure of the flower. The flowers are hermaphroditic with male (stamens) and female (pistils) parts in the same flower and usually with five sepals and five petals. The ovary has a single carpel, cavity, and style. The principal unifying feature of the family is the fruit, a pod technically known as a legume. The legume pod is modified in many ways, including flat, winged, thick, thin, straight, coiled, short, long, woody, fleshy, splitting open, or indehiscent to facilitate dispersal by animals, wind, and water.

The family is divided into three subfamilies: Papilionoideae, Caesalpinioideae, and Mimosoideae, identified by their flowers. The Papilionoideae is the largest of the three subfamilies and the most widespread, extending farther into temperate regions. This subfamily can be easily recognized by its butterfly-like flowers. Most of the important legume crop species consumed by humans, including soybean, field pea, chickpea, field bean, and peanut, are in this group.

The subfamily Caesalpinioideae is comprised of tropical or subtropical trees and shrubs. The useful products derived from this subfamily include edible fruits (*Tamarindus indica*), senna medicine (*Senna* spp.), hematoxylon red dye from the logwood tree (*Haematoxylon campechianum*), and resins used in paints, varnishes, inks, plastics, adhesives, and fireworks derived from the copal (*Copaifera* spp.) tree.

The subfamily Mimosoideae includes species of industrial, forage, browsing, and fodder importance, such as *Acacia* spp. (Bisby et al., 2000). The Australian black-

wood (*Acacia melanoxylon*) tree provides useful timber, and gum arabic from the tree of that name (*Acacia senegal*) is used in an array of industrial processes.

### Nitrogen Fixation

Most legumes convert atmospheric nitrogen into nitrogenous compounds useful to plants. Root nodules containing *Rhizobium* bacteria fix free nitrogen for the plants. In return, legumes supply the bacteria with carbon produced by photosynthesis. This symbiosis provides the nitrogen needed by the plants for survival. Root nodules form in all subfamilies except in rare cases among the Caesalpinioideae.

The basic process of nitrogen fixation involves penetration by the *Rhizobium* through the root hairs into the cortex, where cell division occurs. These tetraploid cells produce the nodules that appear on the root surface. The nodule growth and efficiency are influenced by the carbon-nitrogen ratio of the plant and by the presence in the soil of phosphate, calcium, magnesium, molybdenum, and boron. If the nodules are ineffective, the bacteria may be parasitic on the host plant. Effective nodules contain red leghemoglobin, which can be seen when the nodules are cut. Ineffective nodules are usually small, hard, spherical, and a greenish color inside. Legumes produce more nodules in the tropics in acid soils and soils deficient in phosphorus, calcium, and other nutrients than in temperate areas. Many strains of *Rhizobium* occur in nature with multiple hosts, and several *Rhizobium* species occur with one host (Purseglove, 1981). Many scientists suggest inoculating legume seeds with the appropriate strain of *Rhizobium* for best agricultural results. This inoculation technique is accomplished by mixing the *Rhizobium* in water to form a slurry and then adding it to the seed.

### Origin

The primary temperate legumes used for human food include garden pea (*Pisum sativum*), field pea (*Pisum arvense*), winged pea (*Tetragonolobus purpureus*), green bean (*Phaseolus vulgaris*), runner bean (*Phaseolus coccineus*), butter bean (*Phaseolus lunatus*), lima bean (*Phaseolus limensis*), soybean (*Glycine max*), lentil (*Lens culinaris*), and broad bean (*Vicia faba*). These legumes originated in humid, subhumid, cool season, subtropical, semiarid, and temperate areas in diverse regions ranging from Southwest Asia and East Asia to the Mediterranean, Peru, Mexico, and Guatemala (Muehlbauer, 1993).

Common tropical legumes consumed by humans include winged bean (*Psophocarpus tetragonolobus*), jicama (*Pachyrhizus erosus* and *Pachyrhizus tuberosus*), chickpea (*Cicer arietinum*), black-eyed pea (*Vigna unguiculata unguiculata*), and peanut (*Arachis hypogaea*). These tropical legumes originated in areas characterized by humid, semiarid, cool season, subtropical, and tropical climates, primarily including South America, Southwest Asia, Ethiopia, India, Japan, China, and West Africa (Hy-mowitz, 1990).

**History.** Soybean, one of the most popular legumes, is one of the oldest cultivated crops. Cultivated soybeans probably arose from a wild type in Asia and moved to Europe and North America in the eighteenth century. Soybean soon became the third most important agronomic crop in the United States. Cowpeas were introduced to the West Indies and ultimately spread throughout the southern United States after the seventeenth century. Field beans (*Phaseolus* spp.) were cultivated by American Indians at the time of the European discovery of North America and soon were introduced to Europe. The popular peanut, introduced into the United States from Brazil when the colonies were established, was commercially developed in the mid-eighteenth century.

Peas, including garden peas, field peas, broad beans, lentils, and chickpeas, were introduced into the Americas from Europe and the Near East. Jicama is grown in Southeast Asia, Mexico, and Central America. Winged beans were introduced into more than sixty countries, primarily subtropical and tropical, after the mid-1970s.

### Primary Food Legumes

**Soybean (*Glycine max*).** Soybean is the most important legume produced in the agricultural industry worldwide. It is an annual crop, is easy to grow, and is adapted to a temperate climate. A hot weather crop, soybean requires a minimum of 59°F (15°C) for seed germination and mean temperatures of 68–77°F (20°–25°C) for crop growth. Only moderate soil moisture is needed for germination and seedling establishment, but dry weather is essential for dry seed production. Soybeans suffer when the soil is waterlogged, and established plants tolerate drought.

Soybeans should be fertilized with phosphorous, potassium, and micronutrients, and they require typical agricultural field preparation. The important differences among soybean cultivars are day-length response, pest resistance, and production. These varieties are subdivided into groups according to tropical, subtropical, or temperate climate adaptation (Martin, 1988).

Several major obstacles obstruct optimum soybean production. Diseases cause one-eighth of all soybean losses. Noteworthy diseases and their causal agents include bacterial blight (*Pseudomonas glycinea*), bacterial pustule (*Xanthomonas phaseoli* var. *sojense*), and wildfire (*Pseudomonas tabaci*). However, the most devastating diseases are caused by fungi, including brown stem rot (*Cephalosporium gregatum*), stem canker (*Diaporthe phaseolorum* var. *batatatis*), pod and stem blight (*Diaporthe phaseolorum* var. *sojae*), brown spot (*Septoria glycines*), and sclerotial blight (*Sclerotium rolfsii*). Mosaic virus disease, root knot nematode (*Meloidogyne* spp.), and cyst nematode (*Heterodera glycines*) also cause significant soybean losses.

The chemical composition of mature soybeans varies with the cultivar plus the soil and climate conditions.

Generally, the black-seeded cultivars are protein rich with low oil content, and the yellow-seeded types are oil rich with low protein. The nutritional components of dried seeds are 5.0 percent to 9.4 percent water, 29.6 percent to 50.3 percent protein, 13.5 percent to 24.2 percent fat, 14.0 percent to 23.9 percent carbohydrate, 2.8 percent to 6.3 percent fiber, and a large amount of vitamin B. Soybean seeds contain a higher amount of protein than any other pulse and most other foodstuffs.

Soybean oil is about 51 percent linoleic acid, 30 percent oleic acid, and 6.5 percent linolenic acid and is used as a cooking oil, salad oil, shortening, and margarine. Soybean flour is mixed with wheat flour in baked products, such as bread, cakes, cookies, and crackers, and it is also used in ice cream, candy, and pudding. In Asia soybeans are consumed as soybean milk, soy sauce, soups, drinks, breakfast foods, and vegetables. People in eastern Asia eat unripe seeds and dried seeds, and elsewhere these large seeds are consumed as shelled green beans or as dry beans. Both the Bansei and the Green Giant cultivars are among the more popular soybeans. In the West soybeans are a primary ingredient of Worcestershire sauce, made by mixing boiled beans with wheat flour and salt, then fermenting the mixture with the fungus *Aspergillus oryzae* for up to one week. The fermented beans are submerged in brine and exposed to the sun for several months to extract the flavor. In Indonesia boiled beans are fermented with *Aspergillus* and formed into cakes.

Soybeans are used industrially in paints, linoleum, inks, soaps, insecticides, and disinfectants. Soy meal, the residue of oil extraction, is a healthy livestock feed (Purse-glove, 1981). Soybeans are also used in the pharmaceutical and nutraceutical industries. For example, Ensure glucerna, a dietary aid for diabetics, includes soybeans, and Estroven, marketed as a dietary supplement with natural phytoestrogens, contains isoflavones, a group of antioxidants found in both humans and legumes, extracted from soybeans. While isoflavones do not show antioxidant activity in legumes, they serve various roles as protectants, attractants, and repellents. Because of their antioxidant characteristics, it is possible that isoflavones make a healthy contribution to the human diet.

Groceries and other retail stores sell products that contain soybeans in some form, and American and Oriental restaurants offer foods with soybean constituents. In addition, many products sold as dietary supplements or nutraceuticals in health food stores include soybeans.

**Field peas (*Pisum arvense* and *Pisum sativum*).** The green pea type of field pea became a food source in the sixteenth century. Field peas grow during the cool season and develop flowers and seeds as the days become longer. Field peas have a variety of uses, and production has increased worldwide. At the beginning of the twenty-first century, U.S. production was estimated at 200,000 hectares, and Canadian production exceeded that threefold. Major diseases include Ascochyta blight (*Ascochyta*

## GLOSSARY

**Biome**—The world's major communities classified according to the predominant vegetation and characterized by adaptations of organisms to that particular environment

**Carpel**—A single member of a compound seed-bearing flower organ.

**Cortex**—The primary plant tissue between the vascular system and the epidermis of the stem and the root.

**Cover crop**—A crop grown between orchard trees or on fields between cropping seasons to protect the land from leaching of nutrients and erosion.

**Diversity**—Variety of life on the planet.

**Fodder**—Coarse plants harvested whole and cured in an erect position.

**Forage**—Plant matter, fresh or preserved, gathered and fed to animals.

**Green manure**—Any crop or plant grown and incorporated into the soil.

**Hay**—Fine-stemmed plants cut and cured for forage.

**Heme**—Iron-protoporphyrin IX, a ubiquitous prosthetic group structurally associated to many enzymatic, regulatory, transport, and binding proteins.

**Herbivorous**—Animals that consume only plant material.

**Indehiscent**—Remaining persistently closed.

**Lectin**—Proteins or glycoproteins of nonimmune origin that agglutinate cells and precipitate complex carbohydrates.

They are valuable for blood grouping and erythrocyte polyagglutination, mitogenic stimulation of lymphocytes, lymphocyte subpopulation studies, fractionation of cells and other particles, and histochemical studies of normal and pathological conditions.

**Leghemoglobin**—Heme-containing, oxygen-binding protein found in plants.

**Ovary**—The part of the pistil (the seed-bearing flower organ) that contains the ovules.

**Parasitic**—An organism living or feeding on another organism to the detriment of the host organism.

**Pasture**—Land with forage plants used for grazing animals.

**Petal**—A division of the corolla (the inner floral envelope).

**Pinnate leaf**—Compound leaf with leaflets arranged on each side of a common axis.

**Pulse**—Legume plants or seeds used for food.

**Sepal**—A division of a calyx (the outer floral envelope).

**Silage**—Forage preserved in a succulent condition by partial fermentation in a tight container.

**Style**—The portion of the seed-bearing flower organ that connects the stigma and the ovary.

**Tetraploid**—An organism whose cells contain four haploid (4n) sets of chromosomes or genomes.

**Trifoliolate**—Having three leaflets.

*pisi* and *Ascochyta pinodella*), bacterial blight (*Pseudomonas pisi*), and fusarium wilt (*Fusarium oxysporum* f. *pisi*). Significant insect pests are the pea weevil (*Bruchus pisorum*), the pea aphid (*Illinoia pisi*), and particularly the root knot nematode (*Meloidogyne incognita*). The wrinkled-seed types of field peas are canned in the immature stage, and the smooth-seed types are eaten as dried peas.

Field peas are usually grown as winter annuals in regions receiving 450 to 500 millimeters of rainfall annually. Generally, field peas perform best on well-drained soils with pH between 6.0 and 7.5. Nitrogen fertilization is not needed, but phosphorus, potassium, and sulfur are required (Muehlbauer, 1993).

The nutritional components of dried seeds are 10.6 percent water, 22.5 percent protein, 1 percent fat, 58.5 percent carbohydrate, and 4.4 percent fiber. Fresh green peas are about 74.3 percent water, 6.7 percent protein, 0.4 percent fat, 15.5 percent carbohydrate, and 2.2 percent fiber. These legumes are a major source of human dietary protein worldwide but are of minor importance

in the United States. The seeds are consumed as a fresh vegetable and are canned, frozen, and dried. Field pea pods are also edible. Worldwide field pea plants are used for forage, hay, silage, and green manure (Purseglove, 1981).

**Field beans (*Phaeolus spp.*)**. Brazil, the United States, Mexico, and Italy are the leading producers of field beans. In the United States the common field bean is grown primarily in New York, Michigan, and west of the Mississippi River. Suitable for a variety of soil types, beans are a warm season annual crop. The optimum temperature is 63–77°F (17–25°C), and the beans need 120 to 130 days without frost.

Field bean crops require fertilization with phosphorus and potassium, and zinc is often needed in residual amounts. Because beans are planted in warm soil after all danger of frost is past, planting dates vary from early April to early July according to geographic location. Dry beans are harvested after the pods turn yellow and prior to seed scattering (Martin and Leonard, 1967). Field beans are

Legumes are not only a nutritious addition to the diet, they are also attractive as decorative seeds, as this artistic arrangement of lentils and beans demonstrates. © MICHELLE GARRETT/CORBIS.

subject to a wide array of diseases, including bacterial blight (*Xanthomonas phaseoli*), anthracnose (*Colletotrichum lindemuthianum*), and common bean mosaic virus. Insect pests that cause substantial damage and loss are the bean weevil (*Acanthoscelides obtectus*) and the Mexican bean beetle (*Ephialachna varivestris*).

Rich in the amino acids lysine and tryptophane, field beans are one of the most important sources of human dietary protein. Dried adzuki beans (*Phaseolus angularis*), consumed in Japan and China in soups and cakes, are about 21 percent to 23 percent protein, 0.3 percent fat, and 65 percent carbohydrate. Mung beans (*Phaseolus aureus*) are about 9.7 percent water, 23.6 percent protein, 1.2 percent fat, 58.2 percent carbohydrate, and 3.3 percent fiber. The green mung bean pods are edible, and the fried seeds are popular in India (Purseglove, 1981). Flour from the seeds is used in Indian and Chinese foods, and in the United States grocery chains and restaurants offer mung bean sprouts. Rice beans (*Phaseolus calcaratus*) are consumed in India, Burma, Malaysia, China, Fiji, and the Philippines. The beans are usually boiled, and the young

pods and leaves are also eaten. Rice beans are about 10.5 percent water, 21.7 percent protein, 0.6 percent fat, 58.1 percent carbohydrate, and 5.2 percent fiber.

Central Americans consume the green and dried seeds of the scarlet runner bean (*Phaseolus coccineus*). Lima or butter beans (*Phaseolus lunatus*) are eaten fresh, canned, or frozen in the United States. Dried lima beans are 12.6 percent water, 20.7 percent protein, 1.3 percent fat, 57.3 percent carbohydrate, and 4.3 percent fiber. However, the green beans contain about 66.5 percent water, 7.5 percent protein, 0.8 percent fat, 22.0 percent carbohydrate, and 1.5 percent fiber. The mature beans contain the glucoside phaseolitanin, which gives them their characteristic taste. Because the seeds contain hydrocyanic acid, the cooking water should be boiled and changed during preparation to dissipate the acid.

Black grams (*Phaseolus mungo*) are highly prized in vegetarian diets in India. They can be boiled or eaten whole, and they are ground into a flour used to make porridge or baked into bread and biscuits. The green pods

are also edible. Dried black grams are about 9.7 percent water, 23.4 percent protein, 1.0 percent fat, 57.3 percent carbohydrate, and 3.8 percent fiber (Purseglove, 1981).

The most popular and most widely used beans are known as French beans, kidney beans, runner beans, snap beans, and string beans and are sold throughout the world in grocery stores and restaurants. These are the primary protein food in Latin American and tropical Africa, and in Europe and the United States they are grown for the immature pods, which are consumed fresh, canned, and frozen. The popular baked beans are made with any of these types of whole dried beans cooked with tomato sauce.

**Winged bean (*Psophocarpus tetragonolobus*).** The winged bean is a perennial vine that climbs by twining. Usually grown as annuals, the plants flower during short days. Scarifying winged bean seeds induces better germination. Seeds are planted anytime during the year and germinate within five to fifteen days. The plants tolerate various soil types, including heavy, poorly drained, riverbank, sandy, and infertile soils. Organic material in soil promotes successful winged bean growth; otherwise a small amount of mineral fertilizer is generally recommended. While few pests attack winged beans, geese and chickens consume the plants, and damage by cowpea aphids and root knot nematodes has been reported (Martin and Delpin, 1978).

Winged bean leaves, flowers, shoots, immature pods, mature dried seeds, and tubers, which are highly nutritious, are primarily consumed in Papua New Guinea, South Asia, and Southwest Asia. The young, tender pods, sliced or chopped, are eaten raw. The mature dried seeds are especially nutritious because of their high protein content, 30 to 42 percent. These mature seeds can be steamed, boiled, fried, roasted, or made into milk or tofu. The beans contain some antinutritional substances, thus the seeds should always be soaked overnight and then boiled in water until tender. Oil derived from winged beans contains behenic acid, linoleic acid, and tocopherols (vitamin E). Behenic acid reduces the digestibility of winged beans. Tocopherols are antioxidants that improve the utilization of vitamin A in the human body.

Winged bean tubers, which have a protein content of 8 to 20 percent, are eaten boiled, steamed, fried, or baked in Burma and Papua New Guinea. Winged bean sprouts and shoots are consumed raw or cooked. Usually only the top three leaves are eaten. The flowers, steamed or fried, taste similar to mushrooms. The seeds contain several antinutritional phytochemicals, such as trypsin and chymotrypsin inhibitors, amylase inhibitors, phytohemagglutinins, and cyanogenic glycosides. The seed inhibitor activity can be safely eliminated only by moist heat, that is, by soaking the seeds for ten hours and then boiling them for thirty minutes. Both vanilla- and chocolate-flavored milks have been produced from the seeds in Thailand. Scientists have developed snacks of the

## USES FOR LEGUMES

***Senna occidentalis***—Potential bactericidal, pesticidal, and viricidal plant. It also contains tannin, which is an antidiarrhetic, an antioxidant, and an antiviral agent and has cancer preventive potential.

***Crotalaria juncea***—Sunn hemp, known as a multiple-use small-tree crop. It is used in paper making and as green manure and has bactericidal qualities. Sunn hemp contains pectin, which has antidiabetic, antidiarrhetic, antitumor, antiulcer, and cancer preventive potential. Sunn hemp has been used in Iraq to treat psoriasis.

***Mucuna pruriens***—Velvet bean, a green manure crop and a nutraceutical in the United States. The seeds contain L-dopa, which is used in the treatment of Parkinson's disease, beta-sitosterol, a potential anti-inflammatory, antileukemic, antitumor, cancer preventive, and estrogenic agent; gallic acid, a potential antioxidant, antiseptic, antiviral agent, and cancer preventive; and lecithin, a potential Alzheimer's preventive. Velvet bean is also used in India, Venezuela, and Mexico to treat asthma, snake bites, cancer, coughs, diarrhea, mumps, ringworm, syphilis, and tumors and as a scorpion antidote.

tubers sliced thin, fried, and salted or softened in sugar syrup. Immature winged bean pods are pickled in southern India (Martin and Delpin, 1978). *Psophocarpus tetragonolobus* lectin is derived from winged bean seeds and is used commercially in medical diagnostics.

**Jicama (*Pachyrhizus erosus* and *Pachyrhizus tuberosus*).** Jicama is a tuberous legume commonly grown in Mexico on commercial farms and intercropped with maize and beans on smaller farms. It is also monocropped in Thailand, Malaysia, and Hawaii. Jicamas are usually grown from seeds, however, sprouted tubers are occasionally used. In Mexico tuber yields are highest when planted in March and harvested from September to November, and in Hawaii maximum tuber yields occur when planted in September or October and harvested five months later. Thus jicamas require a hot subtropical to tropical climate with moderate rainfall. They tolerate some drought but are sensitive to frost. They attract few pests but occasionally are attacked by the rose beetle (*Adoretus versutus*) and the bean common mosaic virus (Grum, 1990).

The edible portion of jicamas are about 87.1 percent water, 1.2 percent protein, 0.1 percent fat, 10.6 percent

carbohydrate, and 0.7 percent fiber. The tubers are eaten raw or cooked. The young pods from *Pachyrhizus erosus* are prepared like French beans, but the mature seeds and roots of that plant contain a toxic substance known as rotenone. Young pods of *Pachyrhizus tuberosus* are avoided because they have irritant hairs (Purseglove, 1981).

**Chickpea (*Cicer arietinum*).** Chickpea is the major pulse crop in India, where production reaches 7 million hectares. In the United States, chickpeas are primarily grown in California, Washington, and Idaho. These legumes have a high phosphorus requirement, and both potassium and sulfur should be added if the soil is deficient in either. Chickpeas are adapted to dry conditions and generally flourish on well-drained soils of pH 6.0 to 7.5. The major chickpea pests include gram blight (*Mycosphaerella rabiei*), rust (*Uromyces ciceris-arietini*), wilt (*Rhizoctonia bataticola* and *Fusarium orthoceras*), and gram caterpillar (*Heliothis armigera*).

Chickpeas are important in India, where the dried seeds are boiled and the green pods and shoots are prepared in a variety of ways. Flour made from chickpeas is used in many Indian confections. The common chickpea, also called garbanzo bean, is used in the United States primarily in salads and as a vegetable side dish. Dried chickpeas are about 9.8 percent water, 17.1 percent protein, 5.3 percent fat, 61.2 percent carbohydrate, and 3.9 percent fiber (Purseglove, 1981).

**Peanut (*Arachis hypogaea*).** Peanuts, called groundnuts in other parts of the world, are one of the most important crops in the southern United States, primarily in Georgia, Texas, Oklahoma, North Carolina, Alabama, and Virginia. Other leading production countries include India, China, Nigeria, Senegal, Indonesia, and Brazil. An annual crop with a growing season from 1 May to 1 November in the United States, the peanut prefers sandy loam soils. Adequate soil moisture and high temperatures are necessities for seed germination and plant growth. Peanuts respond best when the pH is above 5. The American peanut is classified into three botanical types based on the shape of the nut and growth characteristics: Virginia (bunch and runner growth types), Spanish (bunch growth type), and Valencia (bunch growth type). Crop rotation is recommended because peanut yields are good following cotton or other nonleguminous crops, and applications of lime and potash usually increase yields. Peanuts suffer from cercospora leaf spots (*Cercospora arachidicola* and *Cercospora personata*), stem and peg rots (*Sclerotium rolfsii*), and tomato spotted wilt virus.

Peanuts are consumed by humans throughout the world as peanut butter, in candies, and as cooking oil. Peanut oil is about 53 percent oleic acid and 25 percent linoleic acid. The Virginia peanut is 38 percent to 47 percent oil, and the Spanish peanut is 47 percent to 50 percent oil. Shelled peanuts are about 5.4 percent water, 30.4 percent protein, 47.7 percent fat, 11.7 percent carbohy-

drate, and 2.5 percent fiber. The primary proteins in peanuts are arachin and conarachin, and peanuts are rich in vitamins B and E (Pattee and Young, 1982). Some people have allergenic reactions to certain types of peanuts. The peanut allergens designated as Ara h 1, Ara h 2, and Ara h 3 are glycoproteins with a molecular mass of 63 kilodaltons and are present in raw and roasted peanuts since they are heat stable and may be found in any peanut type. Peanut proteins, including arachin, conarachin, peanut agglutinin, and peanut phospholipase, can also be allergens. Other important phytochemicals in peanuts are protocatechuic acid, which has shown potential antioxidant and pesticidal qualities, and lecithin, which has shown antioxidant activity (Beckstrom-Sternberg and Duke, 1994). A lectin derived from peanuts is used commercially in medical diagnostics.

**Cowpea (*Vigna spp.*).** Cowpeas led U.S. legume production until about 1941, when they were replaced by soybeans, clovers, and other special-purpose legumes. Cowpeas are produced in California on a fairly large scale, and they are cultivated in Africa, southern Asia, and the Mediterranean region of Europe. A short-day, warm-weather crop, they should be planted in warm soil after all danger of frost has passed. However, severe drought will prevent seed formation. Cowpeas grow well in sandy or clay soils with good water drainage. The common black-eyed pea (*Vigna unguiculata*) is by far the most important cowpea variety.

Common diseases include cowpea wilt (*Fusarium oxysporum* var. *tracheiphilum*), cowpea root knot nematode (*Meloidogyne* spp.), charcoal rot (*Macrophomina phaseoli*), and viral diseases. The chief insect problems are the cowpea weevil (*Callosobruchus maculatus*) and the southern cowpea weevil or four-spotted bean weevil (*Mylabris quadrimaculatus*).

### Legumes Cultivated for Phytochemicals

Jack beans (*Canavalia ensiformis*) are cultivated primarily for their phytochemicals. The ripe, dried seeds are about 11.0 percent water, 23.4 percent protein, 1.2 percent fat, 55.3 percent carbohydrate, and 4.9 percent fiber (Purseglove, 1981). Jack bean seeds are the only source of the lectin known as concanavaline-A, which is used in medical diagnostics. Lectins extracted from several other legumes, including sunn hemp (*Crotalaria juncea*), red kidney beans (*Phaseolus vulgaris*), and field peas (*Pisum sativum*), are used in medical diagnostics also. Guar seeds (*Cyamopsis tetragonolobus*) contain galactomannan gum, which is used in food additives; industrials; pharmaceuticals; confectionaries, including cereal, ice cream, and candy (Whistler and Hymowitz, 1979); and nutraceuticals, such as Ensure glucerna.

Kudzu (*Pueraria* spp.) produces isoflavones used in nutraceuticals for natural estrogen therapy, such as Estroven. A nutraceutical known as kudzu root is sold in powder form. Velvet bean (*Mucuna pruriens*) extract is

TABLE 1

**Minor legumes with special-purpose value**

Name		Use		
Scientific	Common	Agricultural	Bioactive	Phytochemical (Pharmacological)
<i>Canavalia ensiformis</i> (L.) DC.	Jack bean	Forage, green manure, pulse	Pesticide	Concanavalin-A (lectin) Canaline (allelochemic)
<i>Crotalaria juncea</i> (L.)	Sunn hemp	Paper, green manure	Bactericide, pesticide	Pectin (antidiabetic, antidiarrhetic, antitumor, antiulcer, cancer preventive)
<i>Mucuna pruriens</i> (L.) DC.	Velvet bean	Green manure	Bactericide, pesticide, viricide	Beta-sitosterol (anti-inflammatory, antileukemic, antitumor, cancer preventive, estrogenic) Gallic acid (antioxidant, antiseptic, antiviral, cancer preventive) Lecithin (anti-Alzheimeran, hepatoprotective)
<i>Rhynchosia minima</i> (L.) DC.	Snout bean	Forage	Fungicide, pesticide, viricide	Gallic acid (see above) Protocatechuic acid (antiasthmatic, antioxidant)
<i>Senna occidentalis</i> (L.) Link	Coffee senna		Bactericide, pesticide, viricide	Tannin (antidiarrhetic, antioxidant, antiviral, cancer preventive)
<i>Tephrosia purpurea</i> (L.) Pers.			Pesticide	Rutin (antidiabetic, anti-inflammatory, antioxidant, antitumor, antiviral, cancer preventive)

marketed as an antiparkinsonian herbal supplement or nutraceutical. See Table 1 for additional legume phytochemicals.

### Legumes Cultivated for Animal Food

Legume species used for forage include *Aeschynomene*, *Desmodium*, *Leucaena*, *Macroptilium*, *Neonotonia*, *Stylosanthes*, *Desmanthus*, *Macrotyloma*, *Sesbania*, and *Trifolium*. Several species, including *Desmanthus virgatus*, *Stylosanthes scabra*, and *Stylosanthes guianensis*, have been tested in the southeastern United States for possible forage production. *Stylosanthes hamata*, *Stylosanthes humilis*, *Macroptilium atropurpureum*, *Macroptilium bracteatum*, *Neonotonia wightii*, and *Lotononis bainesii* are grown successfully as pasture legumes in Australia and show potential for use in the United States (Morris, 1997).

### Other Uses for Legumes

Several legumes have multiple uses as human foods, animal feeds, ornamentals, cover crops, green manure, and erosion control plants. Minor legumes used primarily for cover crops, forage, and green manure worldwide include calopo (*Calopogonium mucunoides*), centro (*Centrosema pubescens*), and tropical kudzu (*Pueraria phaseoloides*) (Morris, 1997).

*Indigofera arrecta* was once cultivated in India for indigo dye, but it declined significantly with synthetic dye

production. In Central Africa, however, indigo dye derived from the plant is still used. Dhaincha (*Sesbania bispinosa*) produces galactomannan gum and is grown also for soil improvement, fiber for paper pulp, fodder, and its ornamental qualities. Lead trees (*Leucaena leucocephala*), similar in growth to mimosa trees, are used for paper products and as cover crops, fodder, pastures, green manure, and ornamentals (Morris, 1997). Other legumes are important in reclamation of mined soils, polluted soils, deforested areas, and soils with poor nutritional conditions (Morris, 1997).

### Legume Traditions

The expression “blackball” comes from the ancient Greek and Roman practice of using beans for voting. A white bean signifies acceptance, while a black bean means rejection. The black-eyed pea is eaten on New Year’s Day in the southern United States to bring good luck for the coming year.

The Navaho-Ramah Indian tribe used an annual clover known as *Trifolium dubium* as a ceremonial medicine. For a dermatological remedy the Iroquois used a wild bean known as *Strophostyles helvola*, and the Pawnees used spider bean (*Desmodium illinoensis*). Bush clover or rabbit foot (*Lespedeza capitata*) was an antidote in the Fox tribe and an analgesic for the Omahas and Poncas. The Cherokees chewed tickseed or trefoil (*Desmodium*

TABLE 2

Ethnobotanical uses of minor legumes			
Scientific name	Common name	Uses	Countries
<i>Canavalia ensiformis</i> (L.) DC.	Jack bean	Kidney and tonic	China
<i>Clitoria ternatea</i> (L.)	Butterfly pea	Arthritis	Philippines
		Scorpion bite	Sudan
		Laxative	Samoa
		Snake bite	Iraq
<i>Crotalaria juncea</i> (L.)	Sunn hemp	Psoriasis	Iraq
<i>Crotalaria retusa</i> (L.)	Rattle box	Fever	Java
<i>Desmodium adscendens</i> (Sw.) DC.	Tick clover	Bronchitis, colic, ringworms, wound	Africa
		Cough	Cameroon
		Laxative	Ghana
<i>Desmodium gangeticum</i> (L.) DC.		Dysentery, fever, tonic	India
<i>Indigofera tinctoria</i> (L.)	Common indigo	Fever, inflammation, laryngitis, mumps, scabies, swelling, dysentery	China
		Antiseptic, fever	Turkey
<i>Leucaena leucocephala</i> (Lam.) de Wit	Lead tree	Fever, typhoid	Bahamas
		Laxative	Dominican Republic
<i>Mucuna pruriens</i> (L.) DC.	Velvet bean	Scorpion antidote, asthma, snake bite, cancer, coffee, cough, diarrhea, mumps, ringworms, syphilis, tumor	India, Venezuela, Mexico
<i>Psophocarpus tetragonolobus</i> (L.) DC.	Wing bean	Boil, tumor	Java
<i>Tephrosia candida</i> DC.	White tephrosia	Insecticide, piscicide	India, Java
<i>Tephrosia cinerea</i> (L.) Pers.		Fever, piscicide, venereal, tumor	Mexico, Guiana, Brazil, Venezuela
<i>Tephrosia purpurea</i> (L.) Pers.		Colic, piscicide	Sudan, Guiana, Mexico
<i>Tephrosia vogelii</i> Hook. f.	Fish poison bean	Insecticide, insect repellent, piscicide	India, Tanzania, Sudan, Africa

*perplexum*) roots for sore gums and mouths. The Mohegans made a blood purifier from rattle box (*Crotalaria sagittalis*) root, and the Delawares treated venereal disease with rattle box root (Beckstrom-Sternberg, Duke, and Wain, 1994). See Table 2 for additional ethnobotanical and multicultural uses of legumes.

**LENT.** The word “Lent” is derived from Old English *lenten*, meaning ‘spring’, the lengthening of days after winter is over. This was a period of spring fasting known in Old English as *Lencten-Fasten*, or in its abbreviated form, as *Lencten* or *Lent*. The ecclesiastical name for this once mandatory period of fasting is the Quadragesimal Fast, or the fast of the Forty Days, in imitation of the forty days of fasting performed by Jesus in the wilderness.

Like other institutions of Christianity, Lent took time to evolve into its full medieval form. Fasting was practiced in the early Christian Church and was viewed as an aid to prayer. Credence was given to the practice by a statement of Jesus: “When the bridegroom shall be taken from them, then shall they fast” (Matthew 9:15). What was called “half-fasting” was practiced very early on Wednesdays and particularly on Fridays to commemorate the passion or crucifixion of Christ. The Friday fast, as well as the Lenten fast, is still practiced by Roman Catholics, Eastern Orthodox Christians, and some Protestants.

Historically, the forty-day fast reaches back to the second century C.E., although forty days were not always required. By the fourth and fifth centuries, the fasting took place on thirty-six days representing the six weeks prior to Easter, minus six Sundays since Sundays were not fast days. Later, four extra days were added to make forty: Ash Wednesday and the three days following it.

The medieval Catholic Church in general took a middle ground on fasting. Those who put too high a value on the merit of fasting were rebuked with the words of St. Paul: “The kingdom of God is not meat and drink, but righteousness, and peace and joy in the Holy Ghost.” Some extremist heretical groups, such as the Montanists in the second century, fasted frequently on bread, water, and salt.

Abstinence involves refraining from certain foods, meat in the case of Lent, and indeed, during the Middle Ages, all animal products, including butter, lard for cooking, and eggs. Many cookery books contained special recipes designed to make use of non-animal ingredients, such as olive oil, almond milk, and dried fruit. But fasting also refers to the number and fullness of the meals one partakes of on fast days. Both practices are subsumed under penance or penitence, which involves contrition and reparation for sin in human life. Since Vatican II, the rules of Lenten fasting for Roman Catholics have been modified, but earlier they were quite elaborate and even published in newspapers so that the guidelines would be clearly set forth. The following regulations were in force during the 1950s.

Everyone over the age of seven was to observe the Roman Catholic Lent with complete abstinence on all Fridays, Ash Wednesday, and Holy Saturday Morning. During these times, meat and soup, or gravy made from meat, could not be used. During days of partial absti-

nence, which included the Saturdays in Lent (except the last one), meat and soup, or gravy made from soup, could be taken only once a day during the main meal. For those over twenty-one and under fifty-nine, only one full meal per day was allowed during the weekdays of Lent. Other meatless meals were allowed only to maintain strength, but could not equal another full meal. Eating between meals was not permitted, except for liquids, but those people whose health or ability to work were seriously affected by fasting could be excused from the regimen. Acts of charity and of self-denial (such as abstaining from alcoholic drinks and amusements) and daily attendance at mass were encouraged.

In 1966, following Vatican II, Pope Paul VI issued his “Apostolic Constitution on Penance” (*Poenitemini*), which gave present shape to the Roman Catholic Church’s practice of abstinence. This papal clarification modified the elaborate rules for Lent. Still, all Roman Catholics between the ages of eighteen and fifty-nine were required to fast on Ash Wednesday and Good Friday. Everyone over the age of fourteen had to abstain from meat on Ash Wednesday, Good Friday, and all Fridays during Lent. Fasting was defined as taking only one meal per day, but with smaller meals permitted. Abstinence for Roman Catholics does not now include meat juices, broths, consommés, soups made or flavored with meat, meat-based gravies or sauces, margarine or lard. Even bacon drippings poured over salads and meat by-products such as gelatin are now allowed. With the permission of the Episcopal Conference, many American Roman Catholics have substituted other forms of penance, such as works of charity or acts of piety, for the other meatless Fridays during the year.

By contrast, Orthodox Christians abstain from all meat products during most days of the Great Lent, and also from fish and animal products—lard, milk, butter, cheese, and eggs—together with wine and oil during Holy Week. The rigor and austerity of Orthodox fasting remains unchanged and follows the proscriptions of the early Church and its ecumenical councils. For the Orthodox, there are four main periods of fasting during the year: the Great Fast (Lent), the Fast of the Apostles (starting eight days after Pentecost), the Assumption Fast (from 1 to 14 August), and the Christmas Fast (from 15 November to 24 December). There are also a number of lesser fasts that fall outside the Lenten period.

Protestant attitudes to Lent range from complete rejection by denominations of Puritan and Pietist origin, to a rather full acceptance by Anglicans and Lutherans, who retain many practices similar to those of Catholicism. Even the Church of the Brethren, which in its sectarian, separatist beginnings opposed any celebration of the liturgical year, in the late twentieth century began, in some of its congregations, to hold special services on Ash Wednesday and the Sundays of Lent. Such services highlight repentance and prayer, but there are no special Lenten restrictions on food. There has been a movement

among most of the Protestant churches to find common ground during Lent with such community-wide observances as the World Day of Prayer on the first Friday of Lent, and the One Great Hour of Sharing on the fourth Sunday of Lent with offerings dedicated to relieving world hunger.

In order to relieve the dietary austerity of Lent, and to enrich the formerly meager and restricted meals, special Lenten dishes developed in nearly all branches of Christianity. In the United States, they often appear in ethnic markets or in supermarkets catering to certain ethnic groups. One common theme is desserts, with sweet foods taking the place of meat. Recipes for Lent were once commonly published in the spring issues of women's magazines as well as in the food columns of daily newspapers. Cookbooks such as Florence S. Berger's *Cooking for Christ* (1949) and William I. Kaufman's *The Catholic Cookbook: Traditional Feast and Fast Day Recipes* (1965) generally include sections on Lenten meals and recipes that have been found acceptable under the canon law of the Roman Catholic Church.

**LESLIE, ELIZA.** Eliza Leslie (1787–1858) was an American cookbook writer, poet, editor, and author of fiction and nonfiction for children and adults. Although her primary literary activity focused on *belles lettres*, Eliza Leslie is remembered today mainly for the cookery books that launched her career as an author and earned her a national reputation as one of the most popular and influential American food writers prior to the Civil War.

In 1828, Leslie edited and published *Seventy-Five Receipts for Pastry, Cakes and Sweetmeats*, a collection of recipes she had compiled many years earlier while a student at the cooking school of Elizabeth Goodfellow in Philadelphia. The book was an instant success and quickly assumed its place as the first bestselling cookbook in the United States. This was followed by *Domestic French Cookery* (1832), *Directions for Cookery* (1837), *The Lady's House Book* (1840), *The Indian Meal Book* (1846), the first cookbook devoted entirely to corn recipes, *New Receipts for Cooking* (1854), and *The New Cookery Book* (1857), this last title being a massive reworking of her *New Receipts*. Many of these books popularized regional American foods (such as terrapin and okra) at a time when America was searching for a more distinct culinary identity. Of these, *Directions for Cookery* is generally considered Leslie's most influential culinary work, since it remained in print well into the 1880s.

Portrait of Eliza Leslie from a copper engraving originally published in *Godey's Ladies' Book*. The engraving is based on an undated oil portrait by Thomas Sully in the collection of the Pennsylvania Academy of the Fine Arts, Philadelphia. ROUGHWOOD COLLECTION.

## OKRA SOUP

Take a large slice of ham (cold boiled ham is best) and two pounds of lean fresh beef. Cut all the meat into small pieces. Add a quarter of a pound of butter slightly melted, twelve large tomatas pared and cut small, five dozen okras cut into slices not thicker than a cent, and a little cayenne pepper to your taste. Put all these ingredients into a pot, cover them with boiling water, and let them stew slowly for an hour. Then add three quarts of *hot* water, and increase the heat so as to make the soup boil. Skim it well and stir it frequently with a wooden or silver spoon.

Boil it till the tomatas are all to pieces and the okras entirely dissolved. Strain it, and then serve it up with toasted bread cut into dice, put in after it comes out of the pot.

This soup will be improved by a pint of shelled lima beans, boiled by themselves, and put into the tureen just before you send it to table.

**FROM:** *Directions for Cookery*, 32–33. Philadelphia: Carey and Hart, 1837.

Eliza Leslie's success has been attributed to several factors working in tandem: improved female literacy; a growing urban middle class in need of instruction on points of cookery according to American taste and ingredients; and the proliferation of the cookstove, the technological revolution upon which all of Leslie's recipes are based.

**LETTUCE.** Lettuce has been described as a “weedy Cinderella” by T. W. Whitaker (1974) and as the “queen of the salad plants” by Franklin W. Martin and Ruth M. Ruberté (1975). What is this plant that merits two such disparate descriptions? It is certainly the most commonly used salad vegetable, occurring in or under most salads. Many types exist, varying in size, form, leaf shape, color, and taste. All of these types may have evolved from a

weedy form that was used in ancient Egypt as a source of cooking oil from pressed seeds, so both descriptions are probably justified.

Among the several lettuce types, most of which are consumed as raw leaves, one is used for its stem instead of its leaves. This lettuce is depicted on the walls of tombs dating back to about 2500 B.C.E., during the Middle Kingdom of ancient Egypt. Lettuce is shown as a long stem with marks indicating where leaves had been removed. At the top of the stem is a tuft of elongated leaves, bluish green in color. This lettuce may have been the one that first was eaten and may have been derived in turn from the type used for seed oil. The blue color is associated with the process in the growth of lettuce called bolting or stem formation. Leaves that form in the development of the head are green. As the process of bolting begins, the leaves become bluish green, signaling the elongation of the stem, which emerges from the interior of the head and eventually produces many small, yellow flowers that mature into small, narrow fruits. The fruits are less than four millimeters long. They look like seeds and usually go by that name.

Oilseed lettuce is a primitive, wild-looking plant that forms no head or rosette of leaves. It bolts early in its growth cycle, forming a thin stem with elongated, narrow leaves. The seeds produced on this stem are about 50 percent larger than those formed on cultivated lettuce. The seeds are pressed to express an oil used in cooking. This is an ancient custom still practiced in twenty-first century Egypt.

### Evolution of Lettuce

One can speculate that somewhere in time ancient Egyptians selected, perhaps from oilseed lettuce, plants that bolted more slowly and formed a thick stem that was less bitter than the more primitive type and therefore edible. This new stem lettuce also had somewhat broader leaves. Later, perhaps many centuries later, further selection may have yielded a newer form with a still shorter stem and broader leaves that were appealing enough to eat, the romaine type. From Egypt, romaine lettuce moved around the Mediterranean Sea and to the Middle East. In these areas it was the most commonly grown lettuce in the twenty-first century. The original stem type traveled eastward, eventually reaching China. Numerous mentions of lettuce in ancient literature, beginning with Herodotus in 550 B.C.E., document its travels into Persia, Greece, Rome, and Sicily and later into France, Germany, and England. Use of descriptive names, such as *crispa* and *purpurea*, and place names, such as Cappadocian and Cyprian, indicate further proliferation into various distinctive types differing in color, size, leaf shape, and adaptation to specific environments. The various modern butterhead, leaf, and crisphead forms undoubtedly were selected and developed as lettuce spread through Europe. Lettuce reached the shores of the New World with the second voyage of Christopher Columbus in 1494. Many

Chadwick's Rodan is a variety of lettuce developed in England for small kitchen gardens. It was created by Alan Chadwick, the "father" of organic gardening. PHOTO ROB CARDILLO.

varieties within the different types were brought to the Western Hemisphere in subsequent years.

The scientific name of lettuce is *Lactuca sativa*. *Lactuca* means 'milk forming', *sativa* means 'common'. It is related to over one hundred wild species of *Lactuca* and also to sunflower, artichoke, aster, and chrysanthemum. Among the modern types of lettuce are two crisphead forms, iceberg, which forms a large, firm head, and Batavia, which is slightly softer and smaller than iceberg and is popular in Europe. Romaine lettuce has long leaves in a loaf-shaped head. Butterhead lettuce is quite small with oily, soft textured leaves. Red and green leaf lettuces form no head and have leaves with a variety of shapes. Less commonly found are the Latin type, which looks like a small romaine, and the aforementioned stem and oilseed lettuces.

### Preparing a Salad

Since lettuce is used mainly in salads, preparation methods are simple, rapid, and informal. The ubiquitous tossed salad is made of lettuce leaves cut up into various-

sized pieces. To some people the use of a knife is anathema, and they tear the leaves by hand. The salad maker may use one type of lettuce alone or a mixture of two or more kinds. Depending upon the ingenuity of the salad maker and the availability of edibles, any combination of other vegetables, fruits, and even cheeses or meats can be added to the lettuce. A dressing is added, and the ingredients are mixed together. Salads are vital to many slimming diets, the effectiveness of which can be reinforced or negated by the calorie value of the chosen dressing.

In the United States head lettuce was for many years commonly cut and served as a wedge, covered with mayonnaise or another dressing, and eaten with a knife and fork. This simple salad was served less frequently by the beginning of the twenty-first century. The popular Caesar salad is made only with leaves of romaine lettuce tossed with a special dressing, including a raw egg and small pieces of anchovy. A relative newcomer to the salad scene is mesclun, a mixture of baby leaves consisting of several lettuce types and other leafy vegetables, some of which are fairly exotic. These may include arugula or rocket, actually a partially domesticated weed; a fine-leaved endive called *frisée*; mizuna, a small, dark green round leaf from Japan; spinach, beet tops, or chard; red chicory (radicchio); and romaine, butterhead, and red and green leaf lettuces. These leaves are cut in the field by hand, or mowed, when they are no more than ten centimeters long. In parts of the American Southwest wilted lettuce is a favorite salad made by pouring bacon fat over lettuce leaves.

Some salads consist primarily of other vegetables or fruits, such as sliced tomatoes or a scoop of cottage cheese. These are often arranged in a more formal manner than a tossed salad. Lettuce may find its way into these salads as whole or shredded leaves serving as a base for the main constituent.

Lettuce may also be used to make soup, as part of the filling for sandwiches, or as a wrap for holding cooked meat and vegetable mixes. Stem lettuce is consumed raw, like a stalk of celery, in Egypt or as a cooked vegetable in China.

### The Biological Human Connection

Lettuce relates to human biology in several ways. The most obvious way is in its role as a food. Some less well-known relationships to human consumption also exist.

As a green vegetable, lettuce contains many of the same nutrients found in other green vegetables, although mostly in lesser amounts. These include vitamins, minerals, water, and fiber but essentially no protein or fat (Table 1). Lettuce is a low to moderate source of vitamins and minerals. Among the various types of lettuce, romaine and leaf varieties exceed crisphead and butterhead varieties for most of the common nutrients. This is directly related to the proportion of dark green leaves in the edible portion. The nutrient contribution of lettuce

TABLE 1

**Selected nutritional values per 100 grams for crisp, butter, romaine, and leaf lettuces**

	Minerals (g)					Vitamins		Water	Fiber
	Ca	P	Fe	Na	K	A (IU)	C (g)	%	g
Crisp	22	26	1.5	7	166	470	7	95.5	0.5
Butter	35	26	1.8	7	260	1,065	8	95.1	0.5
Romaine	44	35	1.3	9	277	1,925	22	94.9	0.7
Leaf	68	25	1.4	9	264	1,900	18	94.0	0.7

SOURCE: Adapted from Rubatzky and Yamaguchi (1997) as compiled from several original sources.

compared to other vegetables is affected by the amount consumed. For example, a study by M. A. Stevens in 1974 showed that broccoli has considerably more vitamins and minerals than lettuce but that much more lettuce was consumed than broccoli; therefore the total contribution of nutrients to the diet by lettuce was greater than that of broccoli. This relationship may have changed somewhat as consumption habits changed. Nonetheless lettuce is important for its nutrient content, which complements its usefulness as a diet food because of its high water and fiber content.

### Prevention of Cancer

Research in recent years has identified a connection between the consumption of vegetables and certain other foods and beverages and anticarcinogenic activity due to the presence of compounds known as antioxidants. These compounds inhibit the formation of carcinogenic substances in the body. Among the antioxidant compounds in lettuce are 0-beta-carotene, a precursor to Vitamin A, and anthocyanin, which gives the red color in certain lettuce varieties.

The oil pressed from large seeds of certain primitive types of lettuce contributes to a minor food use. The oil is used for cooking and is similar to other oils used for the same purpose. This practice is believed to be hundreds, perhaps thousands of years old.

### Nonfood Uses of Lettuce

Turning to nonfood uses, the stems and leaves of lettuce and its wild relatives contain a milky liquid called latex. The latex contains two substances called sesquiterpene lactones, which are the active ingredients in preparations used in some western European countries as a sedative and as a sleep inducer. In folk medicine additional uses for lettuce extracts include treatment for coughs, nervousness, tension, pain, rheumatism, and even insanity. The efficacy of these treatments is not well documented, but some of these effects have been shown in mice and toads.

Another minor nonfood use is drying lettuce leaves for the production of cigarettes without tobacco. Actu-

ally leaves of a wild relative of lettuce produce a more tobacco-like appearance. These have been manufactured for use in several brands of cigarettes. Effects on health are not known.

Rarely lettuce may impact human biology in a harmful way. Green leafy vegetables are normally the standard for healthful food, providing vitamins and minerals in a fresh, tasty, and light context. Nitrogen is a vital constituent of chlorophyll, the plant substance that gives the green color and controls photosynthesis. However, green leafy vegetables, including lettuce and spinach, when grown under low light and low temperature conditions in greenhouses in the winter, may accumulate high levels of the nitrate form of nitrogen. In the body nitrate may be converted to compounds that may cause the syndrome called blue baby in infants or may be carcinogenic. Fortunately the likelihood of these consequences is remote, since nitrate accumulation in greenhouse-grown lettuce can be prevented by growing the crop with adequate heat and with supplemental light. Lettuce grown outdoors is not subject to this problem.

### Symbolism: Fresh, Cool, Green

The obvious symbolism associated with lettuce is three words, "fresh," "cool," and "green." "Fresh" is a word that many think of as important to health. Lettuce is eaten fresh and raw. In the gardening months many can cut it and eat it almost immediately. It is not that fresh in the store bin of course, but it is still only a few days old. Even the leaves in a packaged salad were growing in the soil shortly before they appeared on the shelf. Lettuce is never frozen or canned.

Lettuce is kept cool. After being cut in the field it is transported to a cooler, where the temperature is quickly reduced to just one degree above freezing. It is transported in refrigerated trucks to a market, where it is kept in a cooler before being placed in a refrigerated bin. Finally, it is purchased by the consumer, taken home, and placed in the refrigerator. This sequence is called the cold chain and is designed to maintain the quality of the lettuce at the time of harvest in the field as long as possible.

Finally, lettuce comes in various shades of green. Even red lettuce contains chlorophyll, which confers the green color, though it may be hidden in the red parts of the leaf. Green means vitamins. Green is a cool color. Many also associate greenness with the health of the planet and with personal health. The process of photosynthesis produces oxygen and sugar converted from carbon dioxide and water. The absorption of carbon dioxide by green plants, from lettuce to trees, helps prevent its accumulation in the air, thus mitigating the greenhouse effect and possible global warming.

The symbolism of these words is so strong that they and similar words, such as “ice,” “crisp,” “winter,” and “spring,” have been used repeatedly in various combinations in the names of lettuce varieties. Consider the names Green Ice, Iceberg, Crisp as Ice, Coolguard, Green Towers, Valverde, Valspring, and Winterset.

In ancient Egypt lettuce had sexual symbolism. After completing its vegetative development with the formation of a head or a rosette of leaves, the plant goes into its reproductive phase with the formation of an erect seed stalk bearing flowers. The amount of latex in the plant increases and is under pressure, so if the top of the flowering stalk is cut off, the latex spurts out in a manner reminiscent of ejaculation. The same tomb paintings portraying the ancient stem lettuce also picture the god Min with an erect phallus. Consumption of lettuce may therefore have been thought to increase sexual prowess.

### **Commercial Production and Marketing**

Lettuce has become a major player in commercial production and marketing. Total production worldwide does not compare with the major cereal crops, especially rice, corn, and wheat, or with other commodities, such as sugar crops, beans, and potatoes, but among the vegetables it ranks high. In the United States it is in the top three with tomatoes and potatoes. The key word in contemporary use of lettuce is change: in use of the various types, in development of world markets, in methods of marketing, and in methods of production.

The primary markets for lettuce were, until the late twentieth century, in western Europe and North America, the consequence of its first appearance in the Mediterranean basin followed by movement into northern Europe and then to the New World. In the late twentieth century lettuce became important in Japan, China, Hong Kong, Australia, and some countries of South America and Africa. In the different regions where lettuce was consumed, one type was usually more popular than the others. In northern Europe, for example, the butterhead type predominated. Until the 1970s about 80 percent of the lettuce consumed in England was butterhead, and the other 20 percent was divided among the other major types. In the countries surrounding the Mediterranean nearly all the lettuce was romaine. Stem lettuce was the main type in Egypt and China. In the United States, until the early part of the twentieth century, no one type was strongly

dominant. At that time crisphead lettuce began to increase in popularity at the expense of the other types. After the modern iceberg lettuce was developed in the 1940s, 95 percent of the production and consumption was of this type. The first modern iceberg variety was created by T. W. Whitaker of the United States Department of Agriculture and was named Great Lakes, although it was actually bred in California.

### **Changes in Consumption Patterns**

In the late 1970s and early 1980s changes in consumption patterns began. In Britain and Scandinavia iceberg lettuce increased in popularity until it became the dominant type. Iceberg lettuce also made inroads into the butterhead and romaine domains in other western European countries. In the United States, where the iceberg type reigned supreme for most of the twentieth century, romaine, butterhead, and leaf lettuces regained popularity and comprised about one-third of the total production at the end of the twentieth century.

The construction of a home-cooked meal has become a casualty of the modern fast-paced lifestyle. People either eat out more frequently or rely on food packages that are partially processed and therefore can be prepared quickly. Salads are included in this drive for efficiency and speed. Modern supermarkets have dedicated extensive shelf space to packaged salads containing what appears to be an infinite number of combinations of leaves (lettuce, cabbage, radicchio, spinach), cut vegetables (carrots, broccoli, cauliflower), dressings, bacon bits, shredded cheeses, croutons, cut fruits, and more.

Changes have also occurred in production methods. Growing, harvesting, and marketing of lettuce is mainly on a large scale, from planting, with significant inputs of water, chemical fertilizers, and appropriate pesticides, to harvesting, cooling, and shipment to market. Production of food with organic methods has become a rapidly growing industry although it is still a small part of the production picture. Lettuce is included in this cultural change. Most of the change has been in the production of nonheading types, such as romaine and leaf lettuce, but some iceberg lettuce is grown in this way. Organic production emphasizes nonuse of chemical fertilizers and pesticides. This type of production began with small-scale growers, but has been included by growers in large-scale production systems.

### **Where Lettuce is Grown**

The need for coolness is a key factor in the location and magnitude of lettuce production areas. In the early twenty-first century the United States was by far the largest producer of lettuce in the world (Table 2). However, few of the fifty states produce lettuce commercially, and of the ones that do California and Arizona are responsible for over 90 percent of the production in the country. California alone accounts for over 70 percent and actually grows lettuce year-round. In the summer let-

TABLE 2

### Commercial production of lettuce in the United States and the European Union

Area in hectares (1 hectare = 2.47 acres), production in millions of metric tons.

	Area	Production
United States (1997)	82,150	3,116
California	57,090	2,243
Arizona	21,900	765
European Union (1996)	90,200	2,351
Spain	33,600	925
Italy	21,300	420
France	13,500	366
United Kingdom	7,500	231
Germany	5,900	144
Greece	3,600	70
Belgium	2,500	85
Netherlands	2,300	110

SOURCE: Compiled from U.S. Department of Agriculture and Eurostat statistics for the years shown.

tuce is produced in coastal valleys near the Pacific Ocean, particularly in the Salinas Valley, which is the most important production region in the world. In the winter lettuce is produced in the desert regions of California and Arizona. For short periods in the spring and fall lettuce is grown in the great Central Valley of California. The coolness of the season is the reason for the movement from location to location. Lettuce grows best when the daytime temperature rarely exceeds 70 to 75°F (21 to 24°C). The desert and inland areas are too hot in summer, while the coastal areas are too cold in winter. Those locations and others with similar seasonal climates in other countries, such as eastern portions of England, the Mediterranean Coast, the Negev Desert in Israel, and the southeastern portions of Australia, produce nearly all the commercially grown lettuce in the world.

Lettuce is grown in home gardens worldwide. In warm climates lettuce growing is usually restricted to the spring and fall, when temperatures are more moderate than in summer or winter. Lettuce grows fast and is easy to grow, especially leaf lettuces, which are the ones most commonly found in the backyard garden.

**LIPIDS.** Lipids (fats and oils) have borne the brunt of the blame for the degenerative diseases (heart disease and cancer) that are the major causes of death in the developed world. The negative view of lipids has obscured their essentiality for human health. If a problem exists, it is one of quantity, in general, and specific lipids in particular.

Lipids are important for maintenance of human health and well-being in a number of ways. Probably the most important function of lipids is provision of an efficient energy source. Fat provides 9 calories of energy per gram or 2.25 times as much as either carbohydrate or protein. Carbohydrate is not stored in the body and protein stores are predominantly muscle, whose breakdown entails serious health consequences. Fat is stored as such and can be easily mobilized if needed. In primitive times survival may have been possible because of energy provided by metabolic use of stored fat (Gurr and Harwood, 1991).

Lipids are a group of substances of diverse structures that share the common trait of being soluble in solvents such as ether or benzene. The major lipids of the body are triglycerides, which comprise a molecule of glycerol to which three fatty acids are bonded. Phospholipids are substances in which glycerol carries only two fatty acids plus phosphoric acid and an organic base such as choline or serine. Cholesterol is a member of the family of large complex molecules generically called steroids. It has the capacity to carry one molecule of fatty acids (cholesteryl ester). Cell membranes are predominantly composed of phospholipids and cholesterol. Cell membranes confer

stability to cells and control entry or release of chemicals into or from the cell. Lipids serve as effective insulators and help in maintaining body temperature. Important organs such as the heart, kidneys, and reproductive organs are cushioned by fat. Nerves are protected by a sheath (myelin) that contains cholesterol, phospholipids, and other lipids. The animal organism carries a number of essential substances that catalyze chemical reactions in cells. These are called vitamins and are designated by letters. The B and C vitamins are soluble in water; the others, vitamins A, D, E, and K, are insoluble in water but soluble in fats. They are transported in lipids in the blood and stored in fat in the body.

### Chemistry

Cholesterol is a molecule that is found in the membrane of every cell. About 0.2 percent of the average body weight is cholesterol. Most of this cholesterol is present in the muscle (cell membrane) or brain (as insulation against trauma). The functions of cholesterol in the brain are still poorly understood. Most of the cholesterol in the body is manufactured in the liver, and the diet makes a relatively small contribution to this pool. Cholesterol, in turn, is the parent substance of a number of vital compounds. Among these are the bile acids that are necessary for proper absorption and digestion of fat; the corticosteroids such as cortisol and hydrocortisone that are essential to life; progesterone which is required for normal reproduction, and the male and female sex hormones. The involvement of cholesterol in the etiology of coronary heart disease will be discussed below.

Fatty acids are chains of carbon acids that culminate in an acidic group called a carboxyl group. Each carbon atom has the capacity to bind four other atoms. In the fatty acid chain, two of those binding elements are bound to the carbon atoms on either side, and the other two are bound to hydrogen atoms. If the hydrogen atoms on adjacent carbon atoms are missing, the two carbons (which are already bound by one bond) form a second bond, and these are called double bonds. A fatty acid lacking the maximum number of hydrogen atoms is called an unsaturated fatty acid. The most common fatty acid in the human body is palmitic acid (16:0, which designates sixteen carbon atoms and no double bonds). Oleic acid (18:1) is the next common fatty acid. The diet provides linoleic (18:2) and linolenic (18:3) acids, which are called "essential fatty acids," meaning fatty acids that are essential to life and health and cannot be synthesized by the human body. Linoleic acid is converted via arachidonic acid to a series of compounds with hormonal activity called prostaglandins. The prostaglandins are usually made within the tissue in which they act and are involved in diverse functions such as control of inflammation, uterine contraction during labor, and blood platelet aggregation. An important group of long-chain polyunsaturated acids (polyunsaturated fatty acids [PUFAs]) occur in the fats of cold-water fish such as salmon and cod. The

two principal PUFAs are eicosapentaenoic acid (20:5) and docosahexaenoic acid (22:6). While these fatty acids do not necessarily affect blood cholesterol levels, their presence in the diet has been associated with a reduced risk of cardiovascular disease. They have been shown to be essential to development of normal vision and also to influence brain development in newborns (Innis, 1991).

Phospholipids are glycerol derivatives in which two of the hydroxyls are esterified to fatty acids and the third to phosphoric acid, which is, in turn, esterified to a base. In lecithin, the most abundant phospholipid, the base is choline. The fatty acid in the 2 position of a phospholipid is usually polyunsaturated. It is often arachidonic acid (20:4), a product of metabolism of essential fatty acid, and a direct precursor of prostaglandins.

### Biochemistry

Blood is an aqueous medium that contains an appreciable amount of lipid. Normal blood serum or plasma appears as a pale yellow, clear liquid, because the fat has been emulsified to give water-soluble fat-protein aggregates. These aggregates are designated as lipoproteins and have a lipid core and a protein coat. Fat enters the lymph in the form of chylomicrons, which are large triglyceride-rich particles. In the course of circulation the triglyceride is deposited in or metabolized by cells and the particles become smaller in size. The lipoproteins can be separated physically on the basis of their hydrated density and are designated as very low-density lipoproteins (VLDL), low-density lipoproteins (LDL), and high-density lipoproteins (HDL). Although estimations of the lipid composition of the various lipoproteins are available, their size and shape may vary.

The proteins surrounding the lipid core (apoproteins) have been characterized and their biological functions catalogued. Thus, apolipoprotein AI (ApoAI) and apolipoprotein AII (ApoAII) are present only in HDL and are required for metabolism of the lipid portion of HDL. ApoAI activates lecithin-cholesterol acyltransferase, which is active in the synthesis of cholesterol esters, and ApoAII is required for breakdown of the triglycerides by lipoprotein lipase.

Apolipoprotein B (ApoB) occurs only in LDL and is required for secretion of the triglyceride-rich lipoproteins. The exclusivity of ApoA and ApoB to HDL and LDL, respectively, is often used for determination of LDL/HDL ratios. Apolipoprotein E (ApoE) is present in both VLDL and HDL. It occurs in several modifications (isoforms), which may determine level of success in treatment of hypercholesterolemia and which have been hypothesized to influence susceptibility to Alzheimer's disease. An LDL variant, Lp(a), appears to confer increased susceptibility to atherosclerosis, and its presence in serum is often used as an additional diagnostic indicator. The principal lipoproteins, LDL and HDL, are known popularly as the "bad" and the "good" cholesterol.

**TABLE 1****Functions of human plasma lipoproteins**

Lipoprotein class	Origin	Function
Chylomicrons	Intestine	Transport lipids from intestine to liver and tissues
Very low density (VLDL)	Liver	Transport lipid from tissues to liver
Intermediate density (IDL)	VLDL	Precursor of LDL
High density (HDL 2 and 3)	Intestine	Remove cholesterol from tissues

Elevated levels of LDL are a risk factor for heart disease, hence LDL is considered to be a “bad” lipoprotein. Elevated HDL levels lower the risk of heart disease, hence the designation “good” cholesterol. LDL is rich in cholesterol and delivers cholesterol into cells, whereas HDL, which is about 50 percent protein, aids in cholesterol egress from cells.

**Heart Disease**

There is a roster of risk factors that are associated with an increased chance of succumbing to heart disease, but none of these factors is an unequivocal risk. Risk in places like Las Vegas is called “odds.” There are a number of well-documented risk factors for development of coronary heart disease. Heredity and age are beyond control. The others are elevated blood pressure, elevated blood cholesterol, smoking, obesity, diabetes, physical inactivity, and stress. Each factor exerts its effects differently in each individual. These factors may also interact. It is now becoming accepted that the initial injury in atherosclerosis may be inflammation, which complicates the risk picture (Ross, 1993). There are suggestions that infection in some way prepares the arterial tissue for the subsequent metabolic events. At present we must monitor the various controllable risk factors, bearing in mind the possibility that a prior event may determine the extent to which the risk factors affect risk. In the United States, deaths from heart disease (cases per 100,000, adjusted for age) peaked in 1968 and have been falling since then. Between 1960 and 1998 mortality from all causes in men fell by 33.8 percent and coronary heart disease mortality by 51.0 percent. In women the reductions were 33.7 and 50.1 percent, respectively. Incidence of the disease may be rising as population increases and other modes of demise diminish or disappear. A century ago the major causes of death were related to infection, while a half-century ago the average age of victims of coronary disease was considerably below what it is today. This is a public health triumph due to improved diagnosis and treatment. The aim now should be to achieve productive and healthy aging.

Of the risk factors cited above none has received more attention than blood cholesterol. Dietary studies related to atherogenesis were conducted early in the twentieth century; they usually involved a combination of dietary alterations plus physical stress. The earliest purely nutritional study was carried out by Ignatowski in 1909. He observed aortic atherosclerosis when weanling rabbits were fed milk and egg yolk or when adult rabbits were fed meat. A few years later Anitschkow (1913) fed rabbits cholesterol and reported atherosclerotic lesions and fat deposition. Anitschkow’s work established dietary cholesterol as the modality for establishment of atherosclerotic-like lesions, and this was carried over to human nutrition; consequently dietary cholesterol was presumed to be the principal contributor to cardiovascular disease. Relatively mild interest in cholesterol and atherosclerosis was evinced in the research and medical communities for the few decades after Anitschkow’s publications. In the late 1940s and early 1950s interest in cholesterol intensified. The reasons for this renewed interest were an increase in death from coronary disease, as death from infectious causes waned and new research findings, especially Gofman’s demonstration of the separation of different lipoprotein classes, which differed in their chemistry (Gofman et al., 1950). The cholesterol-rich lipoproteins were associated with greater susceptibility to heart disease. Subsequently the research area developed the concept of risk factors, of which elevated blood cholesterol was the first clearly defined one. At about the same time epidemiological studies, many conducted by Ancel Keys, began to show that populations whose diets were rich in cholesterol and fat demonstrated high death rates from heart disease.

At this point it might be important to distinguish between the effects of dietary cholesterol and dietary fat. While there is no argument that blood cholesterol is a risk factor for coronary disease, the connection with dietary cholesterol is not strong. The connection between dietary cholesterol and blood cholesterol is controversial. The data show that the amount of dietary cholesterol plays a lesser role in affecting blood cholesterol than does the type of dietary fat. Dietary cholesterol plus saturated fat is much more cholesterolemic than the same amount of cholesterol plus unsaturated fat (McNamara, 1987). Since dietary cholesterol is often accompanied by saturated fat, it is considered prudent to limit its intake. Gertler et al. (1950) reported a study in which they had segregated from a large cohort of coronary patients and controls four groups of ten men each, those who ate the most cholesterol and those who ate the least, and those with highest or lowest plasma cholesterol levels. In every subgroup the coronary patients exhibited significantly higher plasma cholesterol levels than did the controls—thus confirming the role of cholesterol as a risk factor. However, in no group did the investigators find any correlation between dietary cholesterol intake and blood cholesterol level. Thirty years later an attempt was made

to correlate diet with coronary disease in three large populations under continuous study. The populations were in Framingham, Massachusetts; Puerto Rico; and Hawaii. Diets of men who had had a coronary event and those who had not differed significantly in total calories (lower in cases), complex carbohydrate (lower in cases), and alcohol intake (lower in cases). Intake of fat or cholesterol was the same in cases and controls (Gordon et al., 1981).

Type of dietary fat affects atherogenesis in rabbits and cholesterolemia in humans. Keys (1965) and Hegsted (1965) and their colleagues showed that fats rich in saturated fatty acids promoted cholesterolemia. They developed formulas to predict changes in blood cholesterol based on dietary saturated and/or unsaturated fatty acids. Since the publication of the original formulas many revised and refined versions have appeared. The new formulas provide coefficients for specific fatty acids, but none has proved to be more serviceable or useful than the originals. It should be pointed out that even the most saturated dietary fat, coconut oil, contains oleic (about 7 percent) and linoleic (about 2 percent) acids, and that one of the most unsaturated fats, safflower oil, contains about 7 percent palmitic acid and 2 percent stearic acid. In the Keys and Hegsted formulas stearic acid is viewed as "neutral" because it has no effect on blood cholesterol.

An issue that has been debated for several decades is the role of trans-fatty acids. In most naturally occurring unsaturated fatty acids the hydrogen atoms attached to the carbons that constitute the double bond are spatially on the same side of the molecule (*cis*); when they are on opposite sides, they are designated as "trans." There are many trans fats in nature but not many in our usual diet. However, trans double bonds may be formed during hydrogenation of fat used for margarines. The major source of trans fat in the diet is margarine and baked goods made with margarines or margarine stock. Concerns over diets high in trans fats were aired in the 1940s and 1950s. It was found then that in rabbits fed atherogenic diets trans fat elevated cholesterol levels but did not increase severity of atherosclerosis (McMillan et al., 1963). The question of trans fat effects is complicated because hydrogenation may provide fats with double bonds anywhere from carbon 4 to carbon 14 of the fatty acid. Recent research shows that trans fat lowers levels of HDL-cholesterol in humans. It has also been demonstrated that trans fats have little effect in diets containing high levels of polyunsaturated fat. Because of health concerns margarine manufacturers have begun to produce products containing little or no trans-unsaturated fat (Kritchevsky, 1999b).

Ingestion of cholesterol per se appears to have little effect on cholesterolemia. Numerous studies have shown that eggs, the richest source of cholesterol, have little effect on blood cholesterol (McNamara, 2000). However, most cholesterol in the diet is associated with animal fats, which are more saturated than plant fats.

Hence the admonition to exercise prudence in ingestion of cholesterol.

The field of fat and cholesterol is still active and as new fats and new facts emerge dietary suggestions will be modified. At one time we were admonished to eat a virtually fat-free diet, but fat is a necessary nutrient. Very low-fat diets present their own problems, since diets too high in carbohydrate may affect insulin metabolism and can lead to triglyceridemia (Lichtenstein and Van Horn, 1998). In the 1950s high plasma triglyceride levels were considered to be an independent risk factor for coronary disease. For a long while triglyceride levels were virtually ignored, but they are beginning to reassume importance as new clinical and epidemiological data appear. Similarly, the appreciation of specific aspects of fatty acid effects has led to changes in recommendations regarding their intake. At one time the entire emphasis was on polyunsaturated fat, but it was shown that this type of fat lowered both LDL and HDL cholesterol whereas monounsaturated fat (olive oil, for instance) reduced only the "bad" lipoprotein (LDL), leading to a more acceptable LDL-cholesterol/HDL-cholesterol ratio (Mattson and Grundy, 1985). These observations have led to support of the "Mediterranean diet," which is rich in monounsaturated fat but also contains more vegetables and fruit than does the present American diet.

In general terms, current recommendations suggest a diet containing 30 to 35 percent calories from fat with no more than 7 to 10 percent being saturated fat and about 30 to 40 percent carbohydrate, with adequate levels of dietary fiber. Liberal intakes of vegetables and fruit (five to seven servings per day) are also recommended as we begin to find that various plant constituents (carotenoids, flavonoids, phytosterols) may contribute to cardiovascular health. The role of caloric intake is not always addressed directly, but obesity is looked upon as a risk, and daily physical activity is encouraged (Krauss et al., 1996, 2001).

Our view of coronary disease keeps changing with new research findings. Whereas it was originally thought to be simply fat deposition, we now view it as an inflammatory process that can be stimulated by oxidized cholesterol and specific growth factors (Ross, 1993). The initial inflammation may be caused by viral or bacterial infection. The size of the LDL particle may be important; thus small, dense LDL particles may indicate increased risk even in the face of normal lipid levels (Krauss and Burke, 1982). Lipoprotein (a), a slightly altered LDL, affects blood clotting and may be an independent risk factor (Loscalzo, 1990).

The question of established and emerging risk factors has been addressed. The well-established, major risk factors continue to be cigarette smoking, hypertension, elevated serum cholesterol, elevated LDL cholesterol, low-HDL cholesterol, diabetes, and aging. Additional factors that predispose to coronary disease are family history of premature coronary disease (genetics), obesity,

physical inactivity, and psychosocial factors (stress, for instance). Other risk factors are also beginning to appear—some are general and the causative actions of some are not clear. Among these are elevated serum homocysteine levels, first suggested over thirty years ago and possibly connected with metabolism of folic acid and vitamins B<sub>6</sub> and B<sub>12</sub> (Malinow et al., 1999). C-reactive protein (CRP) is a general marker of inflammation produced in the liver in response to bacterial infection or physical trauma. The risk of coronary events is elevated in subjects with elevated levels of cholesterol and CRP (Ridker et al., 1999). Coronary heart disease is related to elevated serum lipids, diabetes, and obesity. All may be influenced by diet but the view of diet becomes more sophisticated and goes beyond dietary fat, although fat still plays a significant role. There is a plethora of risk factors of varying significance, and we still have no unequivocal indication of which subject's risk is affected by which particular factor.

### Cancer

The role of fat in cancer has also been the subject of much research inquiry. In a classic study, Armstrong and Doll (1975) investigated the effects of diet on a number of cancers. Positive associations were found between total fat consumption and colorectal or breast tumors. Animal studies showed that a high-fat diet was more co-carcinogenic than a low-fat diet and that unsaturated fat was more co-carcinogenic than saturated fat. The latter result were due to the fact that linoleic acid is a growth factor for tumors (Carroll and Khor, 1971).

The data concerning fat and cancer risk are inconsistent. High intake of fat is a marker for a high-calorie diet and it is possible that it is the caloric contribution of fat rather than fat itself that is the culprit. Hoffman (1913) suggested that "erroneous diet" was a factor in the etiology of cancer. Excess body weight has been correlated with cancer mortality (Garfinkel, 1985). Animal studies dating to 1909 show that caloric restriction leads to reduced tumor growth. Lavik and Baumann (1943) showed that the incidence of methylcholanthrene-induced skin tumors in mice fed a diet high in fat but low in calories was 52 percent lower than that seen in mice fed a diet high in calories but low in fat. It has also been shown that incidence of dimethylbenz(a)anthracene induced mammary tumors in rats fed 5 percent fat ad libitum is lower than in rats fed a diet containing 20 percent fat but whose energy intake is restricted by 20 percent (Klurfeld et al., 1989).

Epidemiological studies have shown a positive correlation between energy intake and breast or colon cancer risk. The factors underlying the cancer-inhibiting effects of energy restriction are under study. Energy restriction leads to reduction in circulating insulin, and insulin is a growth factor for tumors. Energy restriction also reduced oncogene expression and leads to enhanced DNA repair (Kritchevsky, 1999a).

### Diet

When all of the above has been said, the question each of us must answer remains, "What should I eat?" Dietary suggestions have ranged from the four food groups (meat, carbohydrates, dairy, and fruits and vegetables) to the United States Department of Agriculture (USDA) pyramid. The USDA pyramid is an attempt to illustrate which foods should be eaten in which amounts. The broad base of the pyramid represents large quantities of grains and starches, and the narrow peak represents small quantities of fats and oils. Other dietary components are displayed between the peak and the base and their position in the pyramid represents the relative suggested levels of intake. The idea is to incorporate the best dietary information of the day into a healthful eating pattern. The "Dietary Guidelines for Americans" are written by select committees appointed by the United States Departments of Agriculture and Health and Human Services, and the publication is disseminated under their joint sponsorship. The guideline recommendations have changed relatively little in the past few decades, but the changes that appear reflect current findings and opinion. We are told to maintain ideal weight, although nobody is certain what that means. Originally we were advised to eat a diet that would provide protection against the ravages of infection, but now we are intent on protection against degenerative diseases, heart disease, and cancer, for which we have developed a catalog of risk factors but have no unequivocal diagnoses. Another general factor that we did not have to deal with in the past is the rise in obesity.

Vegetables and fruits provide chemicals that, in the laboratory, protect against cancer and heart disease and provide little or no fat. Grains are part of a healthful diet because they provide complex carbohydrate and fiber. Meat provides high-grade protein, necessary trace minerals (zinc, manganese, iron) and vitamin B<sub>12</sub>, but fear of its fat content is reflected in advice to limit its consumption. Dietary fats are limited because of their caloric content, but they contain the essential fatty acids. Advice about dietary components is presented with the implied view that they are metabolized in a similar manner despite their quantity or presence of other nutrients in the diet. There is virtually no information concerning interaction of individual nutrients.

Fat is feared because of its caloric density and its connection with the risk of heart disease or cancer. The food industry is capable of producing foods that address current concerns. We have available a host of fat-free snacks, but their caloric content is rarely different from the fat-rich food they are replacing. Thus, influence on a risk may be diminished but there is no effect on body weight. Very low-fat diets are criticized as unhealthy. Diets high in carbohydrate may affect insulin metabolism, and there are some investigators who believe that insulin resistance may underlie both cancer and coronary disease.

General dietary advice—enough essential nutrients to maintain health—is constant but the specifics are

distributed on an ad hoc basis depending on current knowledge. A case in point is the avocado. Thirty or so years ago this fruit was not recommended because of its fat content. Today we know the fat is monounsaturated ("good") and the avocado also contains generous quantities of various carotenoids. The avocado is now recommended by nutritionists everywhere. Fat content?—well, just don't eat too much of it. Carotenoids are a family of chemicals that occur in highly colored fruits and vegetables. Some may be precursors of vitamin A. The most common carotenoid is lycopene, which occurs in tomatoes.

To return to the specifics—namely, what we should eat—we still mean a "well-rounded" diet, to be taken in quantities that do not influence body weight. Suggestions to exercise regularly are also becoming part of dietary advice, again for purposes of weight control. Sugary snacks and sugar-rich beverages should be kept to a minimum. The ideal diet, in addition to its content, requires input from the consumer—namely, a measure of discipline.

Healthful diets go beyond "one size fits all." Growing children have different requirements than adults. The elderly may require different levels of various nutrients, and the active elderly have different needs than do the infirm elderly.

So we come down to the general advice of a little of everything but not too much of anything. The advice has to consider age, activity, and health status. Eating should be a pleasurable, social activity and not feared as the specific arbiter of life and death. The best advice for the average healthy person is variety, balance, and moderation. The watchword should be: Moderation, not Martyrdom.

**LIVESTOCK PRODUCTION.** Domesticated livestock have played a pivotal role in the development of human civilizations around the world and continues to be an integral part of human culture, society, and the local and global economy. Domestic livestock has contributed to the rise of human societies and civilizations by increasing the amount of food and nutrition available to people in four ways: by providing sources of meat, milk, and fertilizer, and by pulling plows. Throughout history livestock have also provided leather, wool, other raw materials, and transport.

Livestock furnish high quality protein and energy foods, and function as part of integrated, renewable systems of plant and animal agriculture. The digestive systems of ruminant animals such as cattle, sheep, goats, llamas, and camels are specially adapted to convert plant materials that humans cannot utilize into proteins of high biological availability to humans.

#### **Livestock and the Origins of Civilization**

In his Pulitzer-prize winning book *Guns, Germs, and Steel*, Jared Diamond describes how the availability and husbandry of domesticated plants and animals enabled prehistoric peoples to produce and store sufficient food supplies to develop large, dense societies that did not have to wander in search of food. Agriculture generated the ample, dependable food supply needed to develop specialized, stratified societies, political organization, writing, and technology. Diamond argues that through close coexistence with domestic animals, people in these societies acquired some immunity to epidemic diseases that devastated other populations. His examples include the Spanish conquest of the Inca and other Native American populations, and the near extermination of the Aboriginal peoples of Australia and other regions by British and other European settlers.

#### **DEFINITION OF DOMESTICATED ANIMALS**

Domesticated animals have been modified from their wild ancestors through being kept and selectively bred for use by humans who control the animals' breeding and feeding.

Just five major species of large, plant-eating mammals have been widely domesticated by people for use around the world: sheep, goat, cattle, pig, and horse. Another nine minor species have been domesticated for use in smaller numbers or in restricted geographical areas. These minor species include the Arabian and Bactrian camels, llama, alpaca, donkey, reindeer, water buffalo, yak, Bali cattle of Southeast Asia, and mithan (another bovine descended from the wild gaur) of India and Burma. Under domestication cows, sheep, and pigs have become smaller in size than their wild ancestors. Sheep and alpacas have been selectively bred for fleece characteristics, while cows have been bred to increase milk production. Pigs, cattle, and some sheep have been bred for meat quantity and characteristics. Horses have been bred for specialized purposes including work, war, speed, and riding. Breeds or strains of all the major species have been developed and adapted for specific climatic, physical, and cultural conditions and needs.

Many questions remain about the origins of agriculture, but in most regions archaeologists have found evidence that domestication of plants preceded that of animals by several hundred years. Yet the herding of sheep and goats had become integral to the local economy in areas of the central Levant between eight and nine thousand years ago.

The pastoral societies of Central Asia and reindeer-herding Lapps and Samoyeds of the Arctic are examples of cultures that domesticated livestock, but engaged in little or no cultivation of plants. Augustin Holl, a specialist on western Africa and the advent of food economies, believes pastoralism—herding of animals for food without cultivating plants—was the first form of food production developed by post-Paleolithic groups in regions of the Sahara. Cattle may have been domesticated around ten thousand years ago in Northern Africa.

#### **Evolution of Domestic Livestock through Animal Husbandry**

The ancient Romans developed sophisticated agricultural systems that integrated livestock and crop production, with particular attention to use of animal manures and

### DID AN EARLY SYMBIOSIS OF COWS AND PEOPLE LEAD TO THE CIVILIZATION OF ANCIENT EGYPT?

Anthropologists Angela Close and Fred Wendorf (in *Transitions to Agriculture in Prehistory*) have uncovered a story—of humans and cattle surviving together where neither could likely have survived alone, in the harsh conditions of early Holocene Southeastern Sahara—that illustrates mutually beneficial relationships between humans and cattle. The cattle needed people to find and dig water sources in a region with no standing water. The humans could not have survived without the protein provided by the cattle. Archaeological evidence suggests the cattle were not kept for meat. The authors point out that wild or tame, animals do not have to cooperate with their slaughter for meat, but animals must cooperate for humans to collect animal milk or blood.

People and cattle were able to migrate together to a new area with more resources. Close and University of Rome anthropologist Barbara Barich maintain, as outlined in the January 2000 issue of *Discover*, that these Neolithic Saharans fleeing the desert brought the rudiments of agriculture and of organized, hierarchical society to the Nile Valley, giving rise to one of the earliest great world civilizations. This theory challenges old assumptions about the source of Ancient Egyptian culture and development, and has sparked considerable discussion among scholars in the field.

composts. They developed the art of animal husbandry and selectively bred well-determined breeds of livestock. Their capacity for food production enabled the building of the Roman Empire. Cattle were a significant source of wealth and prestige to the early Romans and to early Germanic peoples. *Pecunia*, the Latin word for money, comes from *pecus*, the word for cattle. The English word “fief” derives from the Old High German word for cattle, *fehu*, denoting the value of cattle for medieval noblemen. Life in the Middle Ages revolved around farming, as the majority of people lived off the land. When hunting became a privilege reserved for the nobility in medieval Europe, livestock became even more important as food sources. But compared to Roman practices, animal husbandry suffered decline during the fifth through the thirteenth centuries. Animals became smaller and less productive with the loss of Roman breeds and selective breeding techniques. Still, the lasting effects of Roman breeding kept medieval stock in the areas of the former Roman Empire superior to those in neighboring regions.

Bökönyi suggests deteriorating climate and crop conditions, changing lifestyles, and devastation of cattle populations by frequent wars as likely causes for the widespread dwarfing of livestock, most pronounced in cattle, which lost 20 centimeters in height at the withers. Beef was the primary meat consumed by the armies of Europe—the origin of the name Beefeaters for the king’s guard. Soldiers drove off any cattle they did not eat.

Bökönyi notes that cattle typical of the early medieval era—small, slender, long-legged, and short-horned—are still found in areas of the Balkans, Anatolia, and the Near and Middle East where animal husbandry largely remains at a medieval level. Early medieval pigs were small, long-legged, and primitive, with skulls similar to the wild boar, with which they could interbreed since domestic pigs roamed freely, foraging in the forests. This approach to pig husbandry continued for centuries, and was common practice in colonial North America. Early medieval horses were more variable, with descendants of Roman horses mixed with large numbers of horses from the East. Horses were similar to modern Asian horses, with slender legs and light trunks. The first coldblood (heavy) horses were selectively bred in Central Europe to carry the weight of a knight in heavy armor.

### The Renaissance of Animal Husbandry

The demographic expansion and rise of urban centers in the Middle Ages could not have happened without an increasingly productive agricultural base, Sweeney argues in his introduction to *Agriculture in the Middle Ages*. The Renaissance in Europe brought the reintroduction of intentional, conscious animal husbandry and breeding, based on classical sources. Farmers and scholars also began to rediscover the value of manure—well documented and practiced by the classical Romans—in fertilizing and rebuilding soils.

Livestock animals grew in size, and increased in productivity, efficiency, and quality. From the fourteenth century to the early modern era (later in Eastern Europe) cattle regained the twenty centimeters in height lost in the early Middle Ages. New breeds of lasting economic consequence were developed, and growth in trade, migration, and exploration brought new domestic species and breeds to various regions around the world. Improved breeds of sheep and cattle yielded higher quality wool and more milk. The excellent meat and stamina for long drives of Hungarian gray steppe cattle, the standard breed in Hungary and neighboring territories by the fourteenth and fifteenth centuries, gained the breed quick popularity through Central and Western Europe, Bökönyi reports.

### Livestock and the Agricultural Revolution 1750–1880

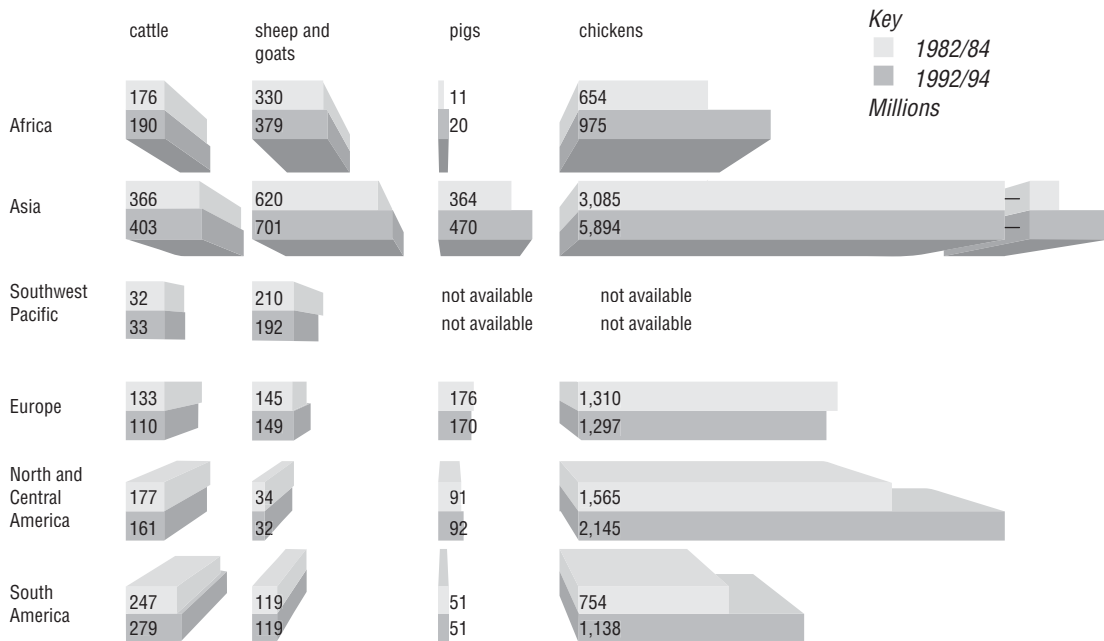

The growth of animal husbandry—including greater use of manure from livestock as fertilizer, was the first of four factors contributing to the Agricultural Revolution that

TABLE 1

Food and Agriculture Organization of the United Nations

FACTFILE

LIVESTOCK NUMBERS

The largest gains in livestock numbers are seen in chickens. Populations of other categories, including sheep and goats, also increased in most areas, especially in the developing world.

ended the cycles of dearth and hunger that had afflicted Europe for centuries (Chambers and Mingay, *The Agricultural Revolution*, p. 4). The Renaissance openness to scientific discoveries, new crops, improved animals, and the resulting productivity gains in agriculture, set the stage for the Agricultural and Industrial Revolutions and the rise of the great cities.

The spread of Merino sheep from Spain is an example. Before the end of the 1700s, Merinos were found throughout the sheep-breeding centers of Western and Central Europe. The first Merinos were brought to New England in 1811. Within two decades the Merino and related Saxony imports, prized for their long-fiber wool, dominated the rising New England woolen industry. Howard S. Russell describes how skilled breeders increased fleeces from only 6 percent of a sheep's live weight

in 1812, to 21 percent by 1865 (*A Long Deep Furrow*, p. 352). Prize breeding stock from Vermont sold for prices in the thousands of dollars. Russell describes how the kinds and populations of domestic animals changed over time in response to market, economic, technological, and social trends and needs in a specific geographical region.

New fodder crops—legumes such as clover, and root vegetables such as turnips—greatly increased the supply and nutritive value of livestock feed. Improved feeding and selective breeding accelerated gains in meat, milk, and wool production. As late as the early 1700s, cattle and sheep—even castrated steers and wethers—took four to five years to fatten, or put meat on their bones. Improved feeding and breeding cut fattening time in half, and by 1800 progressive farmers recognized the value of quality breeding in livestock.

## TWENTIETH CENTURY BRINGS BONANZA IN PRODUCTIVITY GAINS

The twentieth century brought stunning productivity gains, perhaps best illustrated by dairy farming. In 1905 New England was a center of dairy farming, with nearly one million dairy cows on farms throughout the six-state region (Russell, p. 496). In that era, cows produced an average 5,354 pounds of milk in a year. By 2001, the New England milk cow population had declined to 265,800 cows, just 3.1 percent of total U.S. dairy herd. But at over 17,500 pounds of milk per cow per year, the modern cows averaged more than three times the production of their ancestors a century earlier. In the 10 years from 1992 to 2001, milk per cow increased 16 percent in the U.S., while cow numbers declined 6 percent, resulting in a ten-percent increase in total milk production. Over this same ten-year period, the number of dairy farms in the United States decreased by 43 percent, from over 170,000 to fewer than 100,000 dairy farms. (See USDA graphics)

Progress in knowledge and husbandry skills led to specialization in livestock types and breeds, crops, and products. In the 1720s Daniel Defoe described in his *Tour of England and Wales* how farmers in different locales specialized in particular crops such as cereal grains, fruit or hops, on fattening livestock, or dairying. He reported on how the cow-herders of the village of Cheddar cooperated in making their already famous Cheddar cheese.

By 1800 agriculture had become specialized in areas of the United States. Southern New England and eastern New York were already dedicated to dairying, and Connecticut was a center of butter and cheese production and export. Progressive farmers and their associations began importing prize breeding stock from Europe in the early 1800s. Feeding and shelter for livestock improved, especially for milk cows.

### Livestock in the Modern Era

Trends established by the late 1880s continue into the twenty-first century. Lower-priced imports of grain, dairy products, and meat kept prices low, even in times of crop failure, as in 1870s Britain. Yet escalating demand for meat, cheese, and other dairy products encouraged investment and expansion in livestock enterprises. Progress in the art and science of breeding, feeding, health, and care of livestock continues to bring gains in livestock productivity and efficiency. Transportation improvements allow the raising of food-producing animals at greater distances from population centers. Sheep, cattle,

and hog numbers have fluctuated in response to market demand changes and regional comparative advantages.

### Government Protection of Animal and Human Health

To combat severe outbreaks of sheep-rot and of cattle plague (rinderpest) brought by infected cattle imported from Europe in the 1860s and 1870s, the British government restricted the movement of animals and compensated owners for animals slaughtered to control the spread of the diseases, programs first tried in the mid 1700s. In the first half of the 1900s the United States intervened to eradicate livestock diseases such as hog cholera, tuberculosis, and brucellosis in cattle that were transmissible to humans. These tactics remain mainstays of animal disease control efforts.

Commercial pasteurization, introduced in 1895, greatly increased the safety of milk. Improvements in refrigeration and containers further enhanced milk's safety and shelf-life. The serial publication in 1905 of *The Jungle*, Upton Sinclair's muckraking novel about the meat-packing industry, helped lead to government regulation of the food industry. The U.S. Congress passed both the Pure Food and Drug Act and the Meat Inspection Act in 1906, the beginning of federal food safety inspection and regulatory programs.

### Modern Agricultural Trends and the Environment

In response to market demands for lower-cost production, livestock agriculture continues the trend to fewer and larger operations. The U.S. poultry industry became highly intensive and vertically integrated in the last quarter of the twentieth century, with a handful of companies dominating the industry and contracting with growers to raise flocks owned by the companies. The swine industry is experiencing similar restructuring and vertical integration. Intensification and specialization has separated crop production from livestock-raising in many regions, resulting in heightened concerns about environmental impacts, primarily related to manure runoff into water bodies in some areas of Europe and North America. Soil fertility, health, and structure have deteriorated in some crop-intensive areas from lack of livestock manure.

The United States and Europe have increased technical assistance and environmental regulation of livestock operations in response to these concerns. The Clean Water Act legislation of 1972 and 1977 set higher standards of water quality. Less-developed countries have not evolved regulatory or technical assistance programs to address livestock-related pollution.

Sustainable agriculture advocates have sought ways to reintegrate and balance animals and crops to promote soil health and protect natural resources, and have promoted the environmental benefits of practices such as intensively managed grazing. Some dairy, beef, sheep, and other livestock producers have adopted these scientific grazing systems in major livestock-producing regions in-

cluding North America, Europe, Australia, and New Zealand. Government farm programs and subsidies have been increasingly linked to plans and practices to protect soil, water, and wetlands.

### Global Livestock Expansion and Trade

World meat production including poultry totaled 236,991,142 metric tons in 2001, according to the Food and Agriculture Organization of the United Nations. The United States produced 16 percent of the world supply, and the European Union produced 15 percent, while the nations of the Far East produced 35 percent. World milk production in 2001 was 584,651,111 metric tons. The European Union produced over one-fifth, and the United States produced one-eighth of the world milk supply.

China is one of the world's top producers of hogs, beef, poultry, corn, and soybeans. The U.S. Department of Agriculture's February 2002 Agricultural Baseline Projections projected strong growth for the next decade in world beef production, especially in China, Mexico, Canada, and the countries of the former Soviet Union. Brazil, Mexico, China, and Canada are expected to expand pork production. In 2001 Russia was the world's top volume importer of poultry meat, second-highest of pork, and third-highest importer of beef. But Russia, Ukraine, and Kazakhstan have the resource potential to develop into agricultural powerhouses once they establish market economies.

Australia's small population offers a limited market, but its low-cost production capacity limited only by water gives it a competitive advantage in export markets. Australia's herds and flocks fluctuate dramatically in response to world markets.

Brazil and Argentina are major livestock and feed producers. Argentina's exports were temporarily set back by a foot and mouth disease outbreak in 2001. Brazil is expanding livestock production capacity and adopting new technology to increase yields.

Saudi Arabia, Egypt, and Iran import grain to support expanding livestock production. Most Moslem countries prefer meat from home-grown livestock to ensure animals are slaughtered in accordance with Islamic rites.

The U.S. Department of Agriculture expects global trade in livestock products will continue to expand, based on ample global supplies and steady growth in demand. Livestock production is expanding globally to meet demand for meat and dairy products in the growing economies of Asia and Latin America. Livestock development will continue to be a part of economic progress in the developing world.

**LOW COUNTRIES, THE.** At the beginning of the twenty-first century, twelve Belgian restaurants operated in New York City, but only one Dutch restaurant planned an opening. Historically tied together, Belgium and the Netherlands nevertheless developed dissimilar cuisines. During the fifteenth century the area subsequently divided between the two countries became part of the holdings of the powerful duke of Burgundy. With the death of Charles V in 1555, Belgium became a possession of the Spanish Crown. It was part of the Habsburg Empire from the beginning of the seventeenth century until the Napoleonic age. After the revolution of 1578 the Netherlands was an independent republic, confirmed as such in 1648 by the Treaty of Westphalia. In 1813 the two countries were united under King Willem I, which lasted until 1831, when the Netherlands and Belgium, where Flemish, a Dutch dialect, and French are spoken, became separate monarchies. Although the two countries share the Dutch language, they have made different culinary contributions. Belgium's kitchen, akin to the French, is known for its exuberant bistro-style foods that became popular in the United States. The Netherlands' cuisine is more staid, but the country exports fine food products, such as vegetables and cheeses, sought all over the world.

### The Middle Ages and the Renaissance

The first printed cookbook in the Dutch language was *Een Notabel Boecxken van Cokeryen* (A notable little book of cookery). It was published circa 1514, during the time the Low Countries were part of the Burgundian Empire under the reign of Maximilian of Habsburg. The presumed author and publisher is Thomas van der Noot, who belonged to one of the prominent Brussels families.

The book was meant for the well-to-do, the nobility and the high-placed clergy, who could afford the expensive foodstuffs called for in the recipes. As was common for cookbooks at that time, many of the 170 or so recipes were copied from other authors. In this case they were copied especially from the famous French cookbook of the period, Taillevent's *Le Viandier*. The Dutch book includes sauces; fish dishes; ways to prepare meat, poultry, and game, including peacock and pheasant; raised pies; tarts; sweets; and eggs. The recipes are clearly divided into dishes for everyday and those for the church-ordained days of fasting and abstinence, when meat, dairy products, and eggs were forbidden. This prohibition encompassed altogether about 150 days in a year, when only fish, vegetables, and bread were permitted.

Eggs were particularly popular. Said to be the poor person's supper, they often were barely cooked and were slurped from the shell. Milk was cooked in porridges or

custards, some of which were given a pastry base. Milk was preserved as cheese and butter. Unlike in southern Europe, in the Low Countries butter rather than oil was used as a cooking medium.

Several kinds of cheese made of cow's and sheep's milk were marketed in the fourteenth and fifteenth centuries. Cheeses were usually named for the places they came from. The Netherlands is known for its cheeses from the cities of Gouda and Edam. Gouda cheese is made from milk with cream, while Edam-style cheeses are made from skimmed milk and are sometimes flavored with cumin, as in Leyden cheese. By the end of the eighteenth century cumin was replaced in the north by cloves to create Frisian *nagelkaas*. Sheep cheeses were popular early on. Often colored green with sheep feces, these cheeses came from the island of Texel or from 's-Gravensande. As breeding improved and cows produced more milk, more recipes called for milk products, including homemade ricottalike cheeses.

Pork, particularly the fatty parts, was the favorite meat of all classes. Pigs were kept everywhere and generally roamed free. In the fall families who could afford it would purchase a cow that was slaughtered and preserved for winter through salting and smoking.

Cattle, particularly oxen, were imported from Denmark and Schleswig-Holstein in northern Germany. They were herded or transported by ship to Holland for grazing and fattening for slaughter in the grassy meadows of that province. Chickens, ducks, and geese were the common poultry, although songbirds were eaten as well. Deer, goats, and wild boars were among the large game animals hunted, whereas rabbits, pheasants, bitterns, cranes, swans, herons, and ducks were considered small game. The hunt was the privilege of nobility. Falcons and sparrow hawks were trained to catch partridge, geese, ducks, kites, doves, or any other fowl. By the fifteenth century game was reserved more for special occasions than for the daily table of the nobility.

It is often implied that medieval people strongly seasoned their foods because the meats were generally spoiled. That is an unlikely premise. People knew how to preserve foods by drying, smoking, and salting and many regulations concerned the sale of meat. Seasoning was instead more a matter of taste. Spices from the Orient, such as pepper, nutmeg, cloves, and cinnamon, were introduced by way of Venice and became a status symbol for the well-to-do. These spices were mixed with sour verjuice (juice from unripe grapes) or apple juice and some locally grown herbs such as parsley, sage, or savory. They gave the dishes a sharply spiced and sour taste that was popular.

Little is known about the food of the masses. Much of what is known about the food of the period comes from records of the elaborate banquets of the nobility on the occasions of weddings, victories, or coronations. These extravagant medieval feasts consisted of several

courses, each with ten or more dishes, and were known for their between-course happenings. For example, at one of Philips of Burgundy's banquets, an entire orchestra stepped out of a raised pie and started to play.

Fishery was as important to the food supply as to the economy. In the fifteenth century, when the schools of herring moved from the Sont, the strait between Denmark and Sweden, to near the English coast, the Dutch herring fishery bloomed. The development of cleaning and salting herring onboard ship made the fish less perishable. Consequently herring became not only a folk food but also another major trade good for the Low Countries. The salt, which was needed in large quantities not only for preserving herring but also for preserving meat, was imported from France and Portugal. Dried cod, imported from Bergen, Norway, was the main fish eaten by all classes and an important food for the days of fasting and abstinence.

From the rivers the abundant eel were harvested, as were carp, pike, and bream. These were the fish for the more affluent, while the poor and the working classes ate dried plaice, flounder, or whiting. Among its forty or so fish recipes, *Een Notabel Boecxken* describes how to make a brown sauce for a freshly boiled carp. The cooking liquid is mixed with *lebkuchen* (a chewy honey cake), vinegar, and wine and seasoned with ginger, cinnamon, rosemary, quite a bit of sugar, and a little salt.

Castles and cloisters were the centers of horticulture during the Middle Ages. Their gardens provided vegetables, herbs, fruits, and nuts. When, in the second half of the fifteenth century, the sand dunes near Haarlem were removed, fertile grounds became available for horticulture. Through the increased mercantile influence of the large towns, such as Antwerp and Amsterdam, with their expanding markets, horticulture started to flourish beyond castles and cloisters, and by the sixteenth century the Netherlands was known all over Europe for its vegetables. Seeds were cultivated under glass to extend the growth period. Gheeraert Vorselman's *Eenen Nyeuwen Cook Boeck* (A new cookbook) of 1560 was the first to publish salad and vegetable recipes in the Low Countries.

In the Middle Ages, wheat, rye, barley, oats, peas, and beans were grown, but even in the beginning of the period the Netherlands did not grow enough grain to supply its inhabitants. The grain trade developed early on, and by the fifteenth century it was concentrated in Amsterdam. Bread was the mainstay of the diet. It was prepared by bakers, who were organized in powerful guilds. As early as 1341 the government set regulations on bread content, weight, and price. The more expensive wheat bread (called white bread) was eaten by the affluent. Rye bread (called black bread) was the common food for the poor until the second half of the nineteenth century, when through improved transportation methods American wheat, cheaper than the local rye, was imported. At that time wheat bread became the common bread for all.

Beer was the common drink, wine was for the well-to-do, and buttermilk was popular on farms. Beer was brewed at home, but by the fourteenth century the cities of Haarlem and Amersfoort had famous breweries. Cloisters were often known for their brews, and some of the famous Belgian beers hail back to that tradition. The sweeter and less-perishable wines from the Mediterranean countries were popular with the upper classes. The mostly young and white wines, imported from France and Germany, were at that time sour, so they were mixed with honey and spices, such as cloves, coriander, cinnamon, and ginger, to make a drink like hippocras that was enjoyed at the end of a large meal.

Abundant feasts at times of plenty contrasted with the famines of the Middle Ages that wiped out large parts of the population. The Dutch were true trencherpeople who ate and drank immoderately at parties and banquets for guild celebrations; weddings; births, where they would "drown the child"; or funerals, called in jest "grave weddings." Paintings by Brueghel and others depict such events. But the regular meal pattern consisted at most of two meals a day. The main meal, two dishes, was served around eleven in the morning, and the evening meal was one dish. Bread; cheese; root vegetables, like parsnips, carrots, and turnips; cabbage; garlic; onions; peas and beans; fruit in season; porridge; eggs; and a little meat or fish when available were the main foodstuffs.

Mealtimes shifted toward the end of the Middle Ages, when increasingly people ate breakfast. Before meals a water pitcher, a bowl, and a towel or napkin were provided for washing the hands. The plates were first made of bread, then wood, and later tin. The table was covered with a cloth, and bread and salt were placed upon it. The fingers, spoons, or knives were used for eating as the fork was not yet in fashion.

A major change in eating habits came after the Protestant Reformation in the middle of the sixteenth century, when the northern Netherlands largely embraced the Protestant faith as preached by John Calvin and the southern Netherlands remained Catholic. It may be assumed that the Calvinists stopped the days of abstinence immediately, though they continued to eat fish on Friday. Meeting the obligation not to eat meat and dairy products on many days of the year was difficult and expensive. Some medievalists hold that this might be one of the contributing causes of the Reformation's success.

### The Seventeenth Century

The seventeenth century brought prosperity. Both the East India and the West India Companies were founded in its first quarter. Dutch ships brought spices from the Dutch East Indies (now Indonesia) and sugar first from Brazil and then from plantations in the West Indies. Exotic plants, like the pineapple, arrived from every port where Dutch ships docked. With more food available, consumption increased, and the common meal pattern grew to four meals a day. Breakfast consisted of bread

## NEW NETHERLAND

The history of the colony New Netherland begins in 1609. In that year Henry Hudson explored the river that bears his name on behalf of the Dutch East India Company with the aim of finding a northern passage to the Orient. Hudson's explorations established the Dutch claim to a vast area from the Connecticut River to the Delaware Bay. In 1621 the Dutch States General granted a charter with exclusive trading rights in the Western Hemisphere to the Dutch West India Company. In 1626 the island of Manhattan was purchased and settlement began. In 1664 the English took over New Netherland, and with the exception of a brief interlude in 1673–1674, the area remained in British hands until the American Revolution. Yet in only seven brief decades the persistent Dutch settlers entrenched their culture in the country.

Americans eat dishes that can be traced back to the foodways brought by early Dutch settlers. The practical merchants who formed the West India Company intended that the colony should be not only self-sufficient but also able to provision the company's officials and ships engaged in the fur trade and in trade with the West Indies. The settlers brought fruit trees, such as apples, pears, and peaches; vegetables, such as lettuces, cabbages, parsnips, carrots, and beets; and herbs, such as parsley, rosemary, chives, and tarragon. In addition they brought farm animals, such as horses, pigs, and cows. Aboard ship the animals had their own stalls, and often each had an attendant, who would get a bonus when the animal arrived safely.

The new land was fertile. Jacob Steendam, one of the three major Dutch-American poets of New Netherland, called the colony "a land of milk and honey." Adriaen van der Donck, who wrote *A Description of the New Netherlands* (1655) to entice his fellow citizens to settle in the new colony, also was impressed with its fertility. He reports that by the middle of the seventeenth century all sorts of European fruits and vegetables "thrive well" and marvels at the native fish, fowl, and other wildlife available in great abundance.

Trade with the Indians was an important aspect of life in New Netherland. The Dutch traded cloth, beads, and ironware, such as axes and cooking kettles, for

beaver skins. The Dutch also used their baking skills to produce breads, sweet breads, and cookies to trade with the Native Americans. The Indians valued the wheat bread of the Dutch, which previously had been unknown to them. Harmen Meynderts van den Bogaert relates in his diary of 1634–1635 that, when he was more than a day's walk away from Fort Orange, a Mohawk Indian who had just come from the fort offered him a piece of wheat bread. An ordinance for Fort Orange and the village of Beverwijck (now Albany) forbade further baking of bread and cookies for the Indians. Evidently the bakers were using so much flour for this Indian trade that not enough was left to bake bread for the Dutch community. A record survives of a court case in which a baker was fined because "a certain savage" was seen coming out of his house "carrying an oblong sugar bun."

In their new country the colonists continued to prepare the dishes they were used to. Ship records confirm that the West India Company ships brought them kitchen tools, such as frying pans for pancakes or irons for hard and soft waffles. The settlers tried to duplicate life in the Netherlands in New Netherland. However, while they continued their own foodways, they incorporated native foods into their daily diets but in ways that were familiar to them. For instance, they made pumpkin cornmeal pancakes, made pumpkin sweetmeat, or put cranberries instead of the usual raisins and apples in their favorite *oliekoecken*. For lovers of porridge, it was easy to get used to *sappaen*, Indian cornmeal mush, but the Dutch added milk to it. This dish became such an integral part of the Dutch-American diet that it is mentioned on an 1830 menu for the Saint Nicholas Society at the American Hotel in Albany under the heading of "National Dishes." Although many descendants forgot the native tongue, they did not forget the foods of their forebears, and they continued to enjoy the pastries and other dishes connected with feasts and holidays into the twenty-first century. Cookies; pancakes; waffles; *oliekoecken*, a forerunner of doughnuts; pretzels; and coleslaw are among the items the Dutch colonists imported into to America. Vestiges from those original foodways remained in the American kitchen.

and butter or cheese. The noon meal became a stew of meat and vegetables or fish with a dish of fruit, cooked vegetables, honey cake, or raised pie. The afternoon meal of bread and butter or cheese was served a few hours later. Just before people went to bed they ate leftovers from noon, bread and butter or cheese, or a porridge. The poor had a more meager diet.

With the fortunes made in the overseas trade, well-to-do families built country houses away from their city houses, which were usually their places of business also. Country houses had gardens with fruits and vegetables for home consumption and plants from far-away lands. For example, corn was grown as an ornamental and was used in flower bouquets, as still lifes testify. The defini-

tive cookbook of the seventeenth century, *De Verstandige Kock* (The sensible cook), published by an anonymous author in 1667, gives recipes for the homegrown bounty. The book starts with recipes for salads, which were eaten before the meal “to open the stomach.” It gives a full range of recipes for greens; meat; game; poultry; salted, smoked, and dried fish; fresh saltwater and freshwater fish; baked goods; raised pies; and tarts. Separate chapters on preserving meat and fruits end the volume. This was a cookbook for the rapidly developing, affluent burgher class, which, since the nobility had comparatively little influence, was the leading segment of Dutch society. While the peasant diet consisted mostly of bread, milk dishes, vegetables, and meat, the middle classes ate a plentiful diet of varied foods.

The people of the Low Countries were known for their love of sweets. Such treats as sweet breads, like honey cake or gingerbread; or confections, like marzipan, candied almonds, or cinnamon bark, were consumed in addition to the daily fare. Like cheese, Dutch *koek* (*Kuchen* in German) or honey cake was named for its city of origin. By the fourteenth and fifteenth centuries Deventer *koek* from the town of Deventer in the eastern part of the country was famous all over the Netherlands. An important component of the Saint Nicholas celebration on 6 December was another special kind of *koek* named for its chewy texture, *taai taai* or tough dough. All of these cakes were made by professional bakers, who protected their recipes and were united in guilds. Waffles, wafers, and *olie-koecken*, deep-fried balls of dough with raisins, apples, and almonds, were some of the celebratory foods prepared at home, but they were also sold on the streets, as the contemporary artists portrayed.

In the second half of the seventeenth century tea and coffee were introduced, and they had a significant impact on meal patterns and social customs. The East India Company brought tea to the Netherlands first from Japan, then from China through Chinese merchants situated in Batavia. An early shipment in 1610 was considered a curiosity, but as shipments gradually increased, domestic markets developed. Preparing tea required its own paraphernalia, such as small porcelain teacups and small teapots, which were also imported from the Orient. Using a small teapot, an extract of tea was brewed that was diluted with boiling water when served. The small teapots remained in fashion until the nineteenth century, when, according to the English custom, tea was brewed at the required strength directly in a large teapot. Teacups did not have handles until the eighteenth century. Many humorous tales relate the enormous number of cups drunk at the popular late-century tea parties. One woman, admonished by her husband that it was time to go home, told him she could not leave yet because she had only had twenty cups. Tea was served with sweets, like hard candies, marzipan, cookies, and particularly an Utrecht specialty called *theerandjes* (tea cookies), which were strongly spiced

small gingerbread slices. The third meal of the day, which earlier in the century had consisted of bread and butter, was incorporated into the tea ritual and was moved to a later time in the afternoon.

While tea drinking, for which women would gather in the afternoon, had a certain air of high society and snob appeal, coffee was the more public drink. Coffee was consumed in coffeehouses, where men stopped in to have a cup, smoke a pipe, and read the paper. Stefanus Blankaert, an Amsterdam physician and author of a 1686 book on diet, commented on the crowds visiting the coffeehouses in his city. At the end of the century it became the custom of the wealthy to furnish their guests with eating implements, not only a knife and spoon but also a fork. However, it took several decades for the fork to be accepted generally. As late as 1733 a leading journalist argued against its use because, according to a contemporary saying, “God has given us fingers.”

### The Eighteenth Century

The eighteenth century marked greater sophistication in recipes and more variety in dishes offered at one meal. *De Volmaakte Hollandse Keuken Meid* (The perfect Dutch kitchen maid) of 1761 describes in detail how to serve the customary succession of three courses, each consisting of at least ten dishes, and how to place each dish on the table. It was so popular that in 1838 it was reprinted as *De Volmaakte Belgische Keuken Meid* (The perfect Belgian kitchen maid), an updated version that included a section on potato recipes. With some twenty editions spanning the second half of the century, *La Cuisine bourgeoise* (1753) by Menon is an important part of Belgian culinary history.

Fish rather than meat was an important food for the common folk, but oysters and mussels were foods of the rich except in those areas with ready access, such as the Belgian provinces and Zeeland. Game was still the food for nobility, but rabbits became more commonly available.

The more affluent kitchens increased their use of vegetables, including nettles and watercress, abundantly available in rivers and streams. The Italian broccoli was cultivated and was preferred over white cauliflower. Although Carolus Clusius, the founder of the extant botanical garden of Leiden, mentioned the potato plant as early as 1601, potatoes did not enter the popular cuisine until the second half of the eighteenth century. At that time crop failures had made grain expensive and scarce, and cattle diseases had created a lack of milk products. The potato took up the slack and became the most important foodstuff of the poor person's diet. Not until the Napoleonic age, when the economy was failing, did the upper classes include potatoes in their main meals. That was also when the custom developed of not eating bread when potatoes were served. In Dutch restaurants the bread is removed when the main course is served.

Desserts and treats were presented in even greater variety in the eighteenth century. *De Volmaakte Hollandse Keuken Meid* offers a recipe for a luxurious double-crust pie filled with sliced oranges, sprinkled with sugar and cinnamon, and topped with a layer of chopped pistachio nuts. The same volume includes a vast assortment of cookies and sweets, presumably served with tea. The first famous version of the centuries-old *koek* was a simple mixture of rye, honey, spices, and the secret addition of leavening potash made from wood ash imported from the Baltic to make the heavy dough rise. By the seventeenth century *koek* was made all over the Netherlands. The northern parts of Groningen and Friesland were known particularly for their spiced honey cakes with candied citrus fruit peel. But in 1751 the first pastry book, Gerrit van den Brenk's *T'Zaamenspraaken Tusschen een Mevrouw, Banket-bakker en Confiturier* (A dialogue between a lady, a pastry baker, and a confectioner), finally revealed a professional baker's secrets and gave helpful insights into its preparation. By 1750 sugar had overtaken honey as the general sweetener. By that time chocolate had become a

popular drink at home, especially on Saturday and Sunday evenings. Fruit, though seasonal, was eaten by all classes.

### The Nineteenth Century

An even wider difference between the diets of the middle classes and the poor is evident in the nineteenth century. By the end of the century the well-to-do ate meat once or twice a week; only rarely did the worker have meat or, for that matter, fish. An 1869 peat worker's family ate mainly potatoes, rye bread, buckwheat flour, barley, rice, some melted fat, oil, and butter and went without wheat bread, meat, eggs, cheese, or vegetables. They drank a little milk and some coffee. Such unhealthy conditions raised enough concern by midcentury that charitable groups began to establish soup kitchens to provide food for the poor.

The nineteenth century also produced mechanical inventions and a wider selection of cookbooks. Cheese and butter making had been the province of women, but in the 1860s machines took over the work. A machine was invented for kneading rye bread, which up to then, because of its heavy structure, had been kneaded with the feet. While Belgium's most important cookbook of the time, *L'économie culinaire*, written by a Ghent caterer in 1861, enjoyed multiple editions, the main cookbook in the Netherlands, Philippe-Édouard Cauderlier's *Aaltje, de Volmaakte en Zuinige Keukenmeid* (Aaltje, the perfect and frugal kitchen maid), spanned the entire nineteenth century. First published in 1803, it was reissued in 1893. This book presented for the first time the mashed one-pot dishes and the typically Dutch menus of meat, vegetable, and potatoes followed by a dessert made with milk.

Until the nineteenth century the sugar beet was used as cattle feed. But during the Napoleonic age, when the supply of sugar cane was interrupted, the emperor encouraged the fabrication of sugar from sugar beets. By 1812 fourteen such factories operated, but after Napoleon's defeat they disappeared until later in the century.

Changes occurred as well in the general use of beverages. Beer lost its popularity and was replaced with coffee, particularly in the eastern and southern provinces. Tea was more popular in the west, where both beverages were served. The use of *jenever* (juniper-flavored gin) increased dramatically among the working classes, and even hospital personnel received a daily ration of *jenever*. The affluent still drank wine.

### The Twentieth Century

After the industrial revolution and two world wars, the customary meal pattern changed to three meals a day, including breakfast and lunch, of which bread was the major component, and one hot meal in the evening. Coffee breaks in the morning and tea breaks in the afternoon became the common interruptions of the workday. Snack foods, especially French fries and soda, readily available

from corner snack shops or street carts, were consumed anytime. Holiday foods still included *taai taai* and *olie-koecken* (*oliebollen* in modern Dutch). Indonesian restaurants, serving the well-known *rijsttafel* (rice table), became especially popular after World War II. In the year 2000 cosmopolitan restaurants, including America's McDonald's and Pizza Hut, reflected the Dutch trade interests in most countries in the world.

At the end of the nineteenth century and the beginning of the twentieth century, the interest in wholesome foods and the plight of the masses prompted the founding of so-called household schools in both the Netherlands and Belgium. Household schools were intended to instruct working-class housewives in a proper family diet. A better-fed worker could produce more work. But because working-class women had to work, daughters of the middle classes, who were expected to stay home and tend their families as adults, attended these institutions. The teachers did not adjust their curricula or their recipes to the new, higher-class audience. With the goal to simplify and improve, they took away much of the charm, the joy, and some say the taste of the good, centuries-old Dutch burgher kitchen described above. The aim was to create recipes that were considered nutritious and healthful with the right combination of protein, fat, and carbohydrates. Martine Wittop Koning's *Eenvoudige Berekenende Recepten* (Simple calculated recipes, 1901), which went through sixty-two editions, is a prime example. In addition, rather than instructing their students in home cooking from scratch, the teachers encouraged and popularized time-saving, factory-made products in both their classrooms and their cookbooks. The influence of the household schools lasted through several generations, until at least the 1960s. These developments coupled with ever increasing agricultural mechanization and industrialization of food production might explain the demise of the Dutch burgher kitchen. The Netherlands' renowned and outspoken food writer Johannes van Dam also cited them as the explanation for the Netherlands' lesser status as a culinary power. Others look to the lingering trend to think that "one eats to live" coupled with the Calvinist spirit, which frowns on earthly pleasures. Yet others indicate the Dutch commercial inclinations to sell the best products and keep the lesser quality for use at home. The fact remains that, while Dutch foodstuffs are highly sought after and are sold all over the world, its restaurants are not well known.

In contrast, the Belgian kitchen remained true to its French-inspired original. Belgian restaurants have achieved the coveted three-star Michelin status on more than one occasion. Nika Hazelton in *The Belgian Cookbook* (1970) lauds home cooking from scratch. She savors the fish soup from Ghent called *waterzooi* and marvels at mussels *marinière* with white wine, butter, lemon, and parsley. She cannot stop talking about the *friture* or deep-fried foods, particularly French fries, and she toasts the cuisine with a smooth Bruges wheat beer or a Brussels *geuze lambiek*.

The generous custom of treating friends on a person's own birthday rather than being treated is the origin of the expression "Dutch treat." Both countries, Belgium with its restaurants, artisan-made beers, and melt-in-the-mouth chocolates, and the Netherlands with its horticultural products, beers, cocoa, and cheeses, bring the world a true Dutch treat.

**LUNCH.** Lunch, the most informal and unassuming of meals, defies easy definition. A relatively late entry into the cycle of dining, it is replete with socioeconomic forms and meanings. Though the notion of the lunch or luncheon is most often attributed to nineteenth-century Britain, the terms had long been in use in England, albeit in slightly different form. Descended from the Spanish *lonja*, referring to a slice of ham, as the *Oxford English Dictionary* notes, the term has been in use since the Middle Ages as a word for a small snack, often eaten in the fields during the workday and sometimes called *nunchin*. Dr. Johnson's 1755 *Dictionary* defines "luncheon" as "as much food as one's hand can hold." For many centuries, lunch or luncheon was precisely this: a hunk of food, a few hurried bites of sustenance, a snack.

### The Evolution of Meals

The reason for this minor version of the contemporary lunch was simple: For many centuries, the cycle of meals in England was considerably foreshortened. Breakfast was

taken when one rose with the dawn to begin work in an economy that remained largely agrarian and rural. The day's first meal, however, was not originally the elaborate affair that we now identify as the classic British breakfast, and by midday, the medievals were ready for a more substantial repast. This was dinner, the most serious meal of the day for rich and poor alike, involving as much elaboration as one's pocket could afford. For the worker, dinner was meant to help the body recover from the exertions of the morning and to power it through the afternoon's remaining labors. For the rich landowner, it was a marker of ease and privilege and often occupied quite a large portion of the afternoon.

Dinner was generally taken between 11 A.M. and 1 P.M. Dining hours in the medieval period were proscribed both by science and religion. Doctors determined when food might be taken, in what manner and quantity, and in what form. The church also played a role in determining dining hours. In the monasteries of the age, as in contemporary contemplative communities, the hours of the day were divided up according to cycles of prayer; and the monks restricted their dining to the period after prayers at the hour of none, nine hours after dawn. The dining hour in the monasteries moved about, depending on the hour of dawn across the year's cycle. It is from this habit of taking the meal at the ninth hour that the term "noon" is derived, and, thus, the concept of "noon-ing." Noun or verb, noon-ing was not unlike *nuncheon*: Though the meaning of the term shifted about, it referred to a small meal taken at or around the noon hour and was in use in this sense, according to the *Oxford English Dictionary*, as early as 1652.

Not everyone in medieval society adhered to the edicts of doctors or priests, however, and the earliest manifestations of the meal we now call lunch seem to have appeared among the rich and idle. Erasmus's *In Praise of Folly* (published in 1511) describes hard-partying courtiers who slept late but observed the religious forms of the day by having "a wretched little hired priest waiting at their bedside [who] runs quickly through the mass before they're hardly out of bed. Then they go to breakfast, which is scarcely over before there's a summons for lunch." The accumulation of meals is telling: The notion of eating while one was still full from the meal before was thought to be particularly unhealthy, and meals were few and far between in part because the pleasures of dining were, in proper thinking, subordinate to the real occupation of the day—that is, work. By noting that his courtier eats a full meal for this snack, and eats it directly after breakfast, Erasmus emphasizes the morally and physiologically uncertain nature of the lives of the idle rich—and their distance from the strictures of the working world.

### Urbanization and Industrialization

Over time, the hours of dining became increasingly flexible. Urbanization, industrialization, and technology all

played roles in changing the dinner hour. Like much related to the English Industrial Revolution, the transformation of the noon-hour meal progressed at a glacial pace through the eighteenth century and then abruptly picked up speed at the turn of the nineteenth century. In the mid-eighteenth century, dinner was still eaten in the middle of the day. As Horace Walpole wrote in a letter to Richard Bentley in 1753, “[a]ll I will tell you more of Oxford is, that Fashion has so far prevailed over her collegiate sister Custom, that they have altered the hour of dinner from twelve to one. Does it not put one in mind of religion? One don’t abolish Mahommedanism; one only brings it back to where the imposter left it.” But after James Watt’s invention of the steam engine, in 1765, life in England picked up speed in every possible way, and gastronomy was hardly excepted.

One of the most apparent—and arguably most abrupt—of many changes in the socioeconomic landscape of the nation was urbanization. As northern rural land rented for centuries by tenant-farmers was transformed into factories and mines, as families of farmers who had worked common land for generations found themselves without means of support, and as the factory towns offered ever-growing possibilities for employment, a wholesale and unprecedented move to the cities took place across the nation. The mass migration affected every aspect of life, and meals were no exception. Men and women who had lived their lives according to the rhythms of the fields and livestock—rising early to feed animals and work the land before the heat of the afternoon set in, dining heartily in the middle of the day, and taking a small supper (often indistinguishable from breakfast) in the early evening before retiring—found themselves faced with the artificial hours of the factory. In this age before any meaningful regulation of labor, men, women, and children commonly worked twelve- to fifteen-hour shifts on the great factory floors and in smaller, artisanal assembly works. Working days began and ended in darkness, and regularly scheduled breaks were unimaginable. Instead, workers took their food when they could—buying breakfast from a cart on the way to work to maximize their sleeping time (and thus marking the dawn of fast-food culture), and eating a snack—a nuncheon or luncheon—brought from home or bought on the street, in the brief breaks between stretches of work. The abbreviated meal might consist of bread and cheese, boiled bacon, or a bit of pie or oatcake. Like the monks of old, the workers often took this break during the none or noon hour, in the middle of their extended workday.

Urbanization, of course, was not limited to the poor, and the middle class, too, found its meal schedules profoundly affected by the rhythms of the city. The growth of middle management through industrialization brought legions of men into the factory towns of the north as well as into London: men of the newly reimagined middle classes, strivers seeking to better themselves and climb the

social ladder by dint of hard work of the mind. Such men were also deeply involved in the labor of buying, selling, and transport. Britain’s seemingly ever-expanding empire, Parliament’s simultaneous embrace of laissez-faire capitalism and tariff laws, and such new technologies as canning created possibilities for widespread international import and export, so that London’s docks teemed with firms promoting the buying, selling, and shipping of wholesale goods. In these firms, middle-class men sat on upper floors with ink and paper, working columns of figures and making deals in a new kind of labor of the mind, while working-class men dirtied their hands with the work of moving actual product around. Similarly, the eighteenth and nineteenth centuries saw the rise to new prominence of “Change Alley,” home of the stock exchange—the near mythic locus where, then as now, where fortunes might be made or lost in an instant, and place of irresistible temptation for men of little fortune and much ambition. These, then, were the new proving grounds of the middle class: the spaces where strivers might push themselves into the upper echelons, by dint of hard work, good luck, and vast infusions of filthy lucre. The laborers were driven by coffee, often consumed in the coffeehouses of the city: Once the bases for political radicals of the Reformation, these purveyors of speediness and drive were the meeting grounds for movers and shakers. Coffee helped to distance the worker from his body: Divorced from physical fatigue, the entrepreneur and the city man were able to work efficiently and quickly, laboring entirely with the head, not the hand.

The world of the middle-class striver, then, was utterly distanced from the sun-dictated realm of the rural worker: Dawn and dusk became nothing more than markers for those who could work as easily by candlelight as they could by daylight. And as the striver rushed through his businesslike day, urgently buying and selling in the fast-paced world of commerce, he was increasingly unwilling to stop work for a heavy, mind-dulling dinner; nor was he willing to afford his clerks, rising young men themselves, the opportunity to eat and drink themselves into uselessness. Accordingly, the striver began to take his dinner after the workday was done, when the markets were closed and nothing more could be earned. Since coffee alone often proved insufficient fuel for the workday, he grew accustomed to taking a bite of something: a small meal at the coffeehouse or cookshop, a snack from a food vendor in the street, or a bite of bread and cheese, brought from home and eaten at his desk—a luncheon, or, as it was vulgarly known, a lunch.

Urbanization, industrialism, and class mobility, then, all played central roles in the development of a small, relatively casual noontime meal, taken at the once accustomed hour for dining, yet distinct from the more formal and substantial dinner. But the nineteenth-century trend toward lunching was not limited to the laboring classes, and the changing habits of the workingman, ironically, were the driving force behind the changing habits of the

man and woman of leisure. In the country manors and fine town houses, too, the dining hour moved further and further up the clock, creating a substantial alimentary gap in the middle of the day. In some great families, of course, this move reflected the changing working hours of their own city men, lawyers and legislators (and, as the middle classes moved into the realm of the upper crust, the waiting of dinner for the arrival of the great man became increasingly common—hence the late and formal dinners held in the home of Charles Dickens’s businessman Mr. Merdle in his 1854 *Little Dorrit*). For others, however, the late dinner hour was a marker not of labor but of excessive leisure—and, thus, of privilege.

City men, after all, dined late because they came home late from work; they swallowed their dinners and retired to bed soon afterward, ready to do it all again the next day. The elder sons of aristocracy and moneyed gentry, on the other hand, had no such demands on their time, and their schedules, like the fare on their tables, reflected this. For the rich, coffee was consumed at breakfast as an aid to recover from the depredations of the night before; similarly, it was swallowed after a period of after-dinner drinking, with only men present, so that card-playing, dancing, and other entertainments might go on until the wee hours. Dinner, a leisurely meal involving many dishes and, later in the century, many courses, was held late as a marker of sophistication and of wealth. An extensive dinner consumed in the hours of darkness, illuminated by expensive wax candles, was an occasion of glamour for those whose bodies were not bound by the demands of the clock. Let the ordinary working folk dine in full daylight and retire to bed early; those who need not work might gossip and intrigue round the table in the intimacy of candlelight, sup at midnight, and retire to bed in the wee hours—practices that were especially prized during the Regency period, from 1811 to 1820. Technology played a role here as well: While candlelight was certainly adequate for dining, it was hardly ideal for the labor of cooking and cleaning, and so dining at night was difficult for those not equipped with a large staff to deal with the work effectively and the means to light a kitchen well with many candles (or, later in the century, with gaslight). Dining late, then, was in and of itself a marker of means.

Because dinners were relatively public events, at which the rich (*nouveau* and old alike) displayed their wealth with quantities of heavy, preferably imported food and drink, they were, like every public display of wealth, competitive. The constantly shifting markers of true class necessitated ever-increasing demonstrations of deep pockets and cultural currency, one sign of which was the lateness of the hour. Accordingly, “half-gentlemen,” as Jane Austen terms strivers, with pretensions to true gentility, held their dinners late as a means of classing themselves with the sophisticates of the upper echelons, and every time the hour of dining for such ordinary folk moved up, the sophisticates themselves, feeling the com-

petition close in, felt the need to assert their class distinction by pushing their dinner hour later still.

The result of all this, of course, was a need for more meals to fill in the stomach-rumbling spaces between breakfast and dinner—often a gap of some twelve hours or more. The English afternoon or “high” tea evolved around the middle of the nineteenth century, as a genteel late-afternoon sop to the appetite (and, probably, a much-needed dose of restorative caffeine). In the noon-time hour or a little afterward, the gentle classes began to take a refreshment that was more formal and more substantial than a tea, but considerably less extensive than a dinner. In the kitchens and servants’ halls, this meal was referred to as lunch, and was taken as a snack, as it was in the factories. In the dining room, the repast was luncheon.

### The French Influence on Lunch

The prestige of this upper-crust version of the British luncheon was helped along by French cachet. Though gentle Britain was extremely uneasy about the revolutionary developments across the channel, where the aristocracy had been jailed or beheaded, fashionable moneyed Britons nevertheless coveted all things French, and particularly all things French and gastronomic. Gallic chefs, sauces, and dishes were all perceived as both foreign and dangerous, and, thus, as the crucial markers of chic, up-to-the-minute elegance. Luncheon was no exception. Prosper Montagné’s bible of all things gastronomic and French, *Larousse gastronomique*, attributes the development of *dejeuner*, the French precursor to the genteel English luncheon, to the Revolution itself, claiming that the long hours of the new Constituent Assembly, which sat from noon to six, brought about a particular alimentary transformation. According to Montagné, the members of the Assembly obligingly moved their dinner hour (*diner* in French) from one o’clock or so to six o’clock or later, but they soon found that they were unable to work effectively without food from breakfast (*dejeuner*), eaten first thing in the morning, to dinner. To stave off hunger, the members made it a practice to eat a “second breakfast” before their sessions began, around 11:00 A.M. “This second *dejeuner*,” Montagné notes, “was more substantial than the first and included eggs and cold meat.” The practice caught on, and the first *dejeuner* (a meal of soup or coffee with milk) was soon relegated to the status of *petit dejeuner*. The term “lunch” or “luncheon” was introduced into France in the nineteenth century, generally referring to a cold buffet for a large group of people, eaten standing up.

While the French *dejeuner* was driven by the lofty labor of hard-thinking men, the genteel English version was originally a ladies’ amusement: The twentieth-century “lady who lunches” had her cultural birth in nineteenth-century England. Women of fashion and leisure, left at home while their husbands tended to business or pleasure, soon found that delaying their dinner to eight

## LUNCH MENUS

Arnold Palmer quotes Edgeworth's satisfying luncheon of 1823 thusly:

"First course, cold; two roast chickens, better never were; a ham, finer never seen, even at my mother's luncheons; pickled salmon, and cold boiled round. Second course, hot; a large dish of little trout from the river; new potatoes and . . . a dish of mashed potatoes for me; fresh greens, with toast over, and poached eggs. Then, a custard pudding, a gooseberry tart, and plenty of Highland cream—highly superior to lowland—and butter, ditto." He adds, "[f]or this, she was charged six shillings." (Quoted in Allen, p. 180)

Edward and Lorna Bunyard's *The Epicure's Companion* cites a day of ladies' meals in a great house, recorded in the 1857 *Country Hospitality*, or *Lord and Lady Harcourt*, thusly:

Lady Axminster and Lady Rachel had that morning breakfasted on a first course of fish-curry, followed by meat pies, preserves, eggs, chocolate, tea, coffee, and muffins. At luncheon they had revealed on hashed venison, stewed mushrooms, an immeasurable apricot tart drenched in cream, and a bottle of soda water with sherry, but both ladies now declared they felt "quite faint"—a mountain of bread and butter now vanished rapidly, and numberless cups of tea were drained off (p. 422).

A luncheon (probably catered) held by Theodore Mander, a self-made industrialist, to celebrate the opening of the Higher Grade School in Wolverhampton, included the following (Paston-Williams):

Consommé  
Saumon et mayonnaise  
Soufflés de homard à la Montglas  
Dindonneau froid à la Grande Duchesse  
Soufflé à la Marguérite  
Aloyau de boeuf rôti  
Cotelettes de mouton en aspic  
Galantine de volaille  
Pâté de gibier  
Jambon glacé, Langues  
Dindon rôti  
Pièce de boeuf braisée à la Napolitaine  
Faisans, perdreaux  
Gâteau d'abricots  
Gelée à la Russe, gelée à la Française  
Charlotte à l'Alexandra  
Pommes à la Princesse Maud  
Crème à la Munich  
Fruits

o'clock or later left them hungry in the afternoons; they began taking a midday repast, generally at the same time that the servants and children had their dinner. This small luncheon soon turned into an occasion for entertaining, reserved nearly exclusively for women. Arnold Palmer in *Moveable Feasts* cites such luncheons, served at one o'clock in the afternoon, occurring as early as 1818, but notes that this is an aberration. By the 1830s, however, luncheons were increasingly common. The meal was dainty. By the 1850s the practice had spread to the relatively financially stable members of the striving classes, as women who were freed from the real labor of the home by servants filled their afternoons with visiting and eating. The middle-class meal was not always as elaborate as the luncheon of the rich, however: Frugal housewives might make a lunch of leftovers from the last night's dinner or the children's meals, though only when no company was expected. When guests were present, luncheon foods were lighter than the fare of other meals, and because visitors generally retained their bonnets and shawls throughout the meal, the food could not be cumbersome or messy. It was served elegantly but simply. Sara Paston-Williams writes in *The Art of Dining* that by the close of the century, the fashionable table was quite bare: All food except fruit was served from the sideboard by the butler, so that the meal was at the crossroads between utter formality of service and utter informality of appearance. Less dressed-up luncheons featured hot meats on the sideboard, cold sweets in a row in the middle of the table, and other dishes served by the hostess. By the late 1800s, formal luncheons as celebrations and special occasion meals were not uncommon.

As Palmer makes clear, this form of luncheon was generally shunned by men, viewed as a despicable product of daintiness, trendiness, and boredom, a bastion of gossip and irrelevancy. While women's luncheons developed into a full-fledged meal, men tenaciously clung to the original sense of the term, downing a bite or two of wine and a swallow of biscuit, with or without a bit of meat, in a chophouse, at a club, at work, or on the street. For city men in particular, luncheon was public, and thus associated with business; there was nothing of indulgence or leisure about it. As the middle class grew more stable toward the end of the century, however, the practice of the lengthy business lunch, generally held at gentlemen's clubs, gradually caught on.

Gentlemen of leisure, on the other hand, incorporated luncheon into their days in more relaxed ways. They may well, for instance, have taken their cues from French epicureans. Jean-Anthelme Brillat-Savarin, in *The Physiology of Taste*, describes the great pleasures of the "hunting-luncheon," a snack of bread and cheese, chicken, and wine taken beneath the trees, as the epitome of leisure, and thus brings the notion of the courtier's lunch back to the leisured classes, while retaining its implications as a light, unmeal-like meal.

## The Acceptance of Lunch

By the middle of the nineteenth century, the regular luncheon meal had become, if not commonplace, at least commonly accepted among the fashionable. But the trajectory of the meal was by no means clear. Benjamin Disraeli, in his collected *Letters*, refers to luncheon as “my principal meal,” at once marking his own sense of distinction by referring to luncheon and demonstrating his old-fashioned bent, by turning his luncheon, as it were, into dinner. Palmer describes writer Maria Edgeworth’s oscillation between meal cycles as she moves from country house to country house, enjoying a full-fledged lunch of two courses and dessert one day, and reverting to the old-fashioned habit of midday dinner on the next. Lunch was sometimes amalgamated with tea, and taken in the middle of the afternoon. Sarah Freeman declares in *Mutton and Oysters* that “[l]unch as an occasion for entertaining was introduced in the late 1850s,” but the first edition of Isabella Beeton’s *Book of Household Management*, published in 1861, wastes little time on the meal. In her all-purpose guide for the up-to-date housewife, she makes mention of a light, sweet dessert known as a “luncheon cake” but declares it “seasonable at any time.” And though she refers to luncheons in her survey of the well-bred lady’s day as “a very necessary meal between an early breakfast and a late dinner, as a healthy person, with good exercise, should have a fresh supply of food once in four hours,” she devotes scant space to its forms. In a brief section at the end of the book, she advises women to take

[t]he remains of cold joints, nicely garnished, a few sweets, or a little hashed meat, poultry or game . . . with bread and cheese, biscuits, butter, &c. If a substantial meal is desired, rump-steaks or mutton chops may be served, as also veal cutlets, kidneys, or any dish of that kind. In families where there is a nursery, the mistress of the house often partakes of the meal with the children, and makes it her luncheon. In the summer, a few dishes of fresh fruit should be added to the luncheon, or, instead of this, a compote of fruit or fruit tart, or pudding.

For Beeton, in other words, luncheon remained a meal for fuel, rather than an occasion for entertaining and social niceties, and leftovers or nursery food were more than sufficient. This easy dismissal of luncheon may be due, in part, to her focus on helping women become useful helpmates and mothers, rather than fashionable figures: Since luncheon was patently a women’s meal in the home, it could occupy little space in the husband-centered Beetonian oeuvre. Breakfast, on the other hand, warranted a great deal of ink in Beeton’s work, since this was a meal over which men did business, and at which the men and women of the household ate together. And it was substantial: It is easy to imagine that anyone who ate a breakfast of cold meats, broiled fish, chops or sausage, kidneys, eggs, fruit in season, and toast might find themselves not exactly hungry when the luncheon hour came around. Indeed, it is not unthinkable that the

ladies’ luncheon evolved in tandem with the lady of genteel appetites. As women’s eating habits came under increasing scrutiny in tandem with the development of the medicalized and rigorously controlled female body of the nineteenth century (the precursor to our own cultural preoccupation with women’s bodily shapes), any self-respecting lady would restrain her appetites, particularly for strong meats and organ foods, at a meal at which men were present. Thus, it is conceivable that the woman who ate breakfast with becoming propriety would find herself hungry by noon, while her husband, free to eat whatever was before him, could not conceive of such alimentary weakness.

However, Beeton’s neglect of the meal also signals its still-precarious position in the pantheon of meals at midcentury. In mealtimes, as in the realms of work and fashion, nineteenth-century England seemed to exist in several periods at once: The old-fashioned dinner sat alongside the newfangled luncheon, and the two meals were sometimes taken, as Beeton notes, at the same moment by members of various echelons of the household (servants and children dined while ladies lunched). Participation in one regime or the other marked the eater: The luncher was urban or, at least, in touch with the latest London fashions; female; young or progressive in her style; and wealthy, or hoping to be taken as such.

By the end of the nineteenth century, the luncheon was well-established in English society; the 1899 edition of Beeton’s *Book*, for example, gives a full seven pages to luncheon forms, etiquette, and menus. Even at this late date, however, confusion remained. Beeton introduces her section on luncheon by remarking that “[u]nder the above name come a very great variety of meals; for we have no other name for the one that comes between breakfast and dinner. It may be a crust of bread and butter or cheese, or an elaborate meal of four or five courses; it is still ‘luncheon.’ Also it may take place at any time. The lower classes lunch between 10 and 11; the upper, some three or four hours later.” Everyone, it seems, found a lunch of some sort necessary by the close of the century: the chasms between rich and poor, man and woman, urban and rural had more or less closed on this point. And despite the confusion over the hour and contents of luncheon, the meal remained an informal one, generally lighter than either breakfast or dinner. Through the Edwardian period, lunch became a lighter meal, similar to contemporary imaginings of the repast, and more generally indulged in by both men and women.

The end of the century also saw the advent of brunch, a meal closely associated with the Oscar Wilde-esque dandies of the period. The *Oxford English Dictionary* notes that the word was originally university slang; *Punch* magazine attributes the term to Guy Beringer, writing in *Hunter’s Weekly* about a meal that combined breakfast and lunch—and was presumably indulged in by university rakes and other men about town who slept through breakfast, exhausted by the exertions of the night

## MRS. BEETON'S INSTRUCTIONS FOR A PROPER LUNCHEON

The 1899 edition of Mrs. Beeton's *Book of Household Management* includes instructions for laying a proper luncheon table, guidelines for menu construction, and a warning to avoid extravagance at this most informal of meals. The book offers a number of menus for luncheons with guests, picnic luncheons, and "family luncheons."

On a Monday in summer, a family might lunch on "[m]utton cutlets and peas, cold chicken, ham, salad.—Gooseberry fool, cold milk pudding.—Bread, cheese, butter, biscuits." On a Saturday, the menu might include "Minced beef or any other cold meat, Russian salad.—Macaroni cheese.—Cake, fruit, bread, butter, biscuits." A winter family menu might consist of "Curried cold fish, steak fried, mashed potatoes.—Tinned pine.—Custard.—Bread, butter, cheese, biscuits." (Note the marks of technology and of Empire: curries from India, generally stripped of much of their spiciness, became standard fare on British tables during the nineteenth century, and canned goods were at once economical and alluring in their factory-stamped newness.) A Thursday winter family lunch, on the other hand, might be based around a "[j]oint from servants' table with vegetables"—incorporating both economy and good old English style, as the plain joint—a well-cooked piece of meat without fancy foreign sauces—was the epitome of old-fashioned English fare. It could be accompanied by "[a]ny cold pudding.—Cake, preserve.—Bread, butter, cheese, biscuits." (p. 246)

An "economical luncheon" was much more limited, incorporating one main course, one simple dessert, and bread with butter, cheese, or marmalade; the main course might consist of "rissoles of cold meat" or "potato pie made from remains of cold meat" (p. 247). The inclusion of such recipes demonstrates the reach of luncheon through every class.

\*

A luncheon for guests was somewhat more elaborate. The 1899 edition of Beeton lists the following menu for a summer repast for ten:

Cold salmon, tartar sauce, cucumber  
Roast chicken, potatoes, green peas  
Cold lamb, salad  
Raspberry and current tart (cold), custard  
Maraschino jelly  
Strawberries and cream  
Bread, butter, cheese, biscuits, &c. (p. 245)

In winter, Beeton's *Guide* suggests the following:

Clear soup  
Fried soles, caper sauce  
Hashed turkey, cold roast beef, beetroot, mashed potatoes  
Pheasants  
Sweet Omelette, stewed prunes and rice (cold), cheese, celery  
Pears, oranges  
Bread, butter, &c. (p. 245)

In 1934 Florence B. Jack's *Cookery for Every Household* offered a series of seasonal menus for "the luncheon proper, which resembles the French déjeuner in style" (p. 674). While noting that dishes might be added or subtracted depending on appetite and occasion, she generally proposes menus of four courses, including the following:

For spring: spring soup, mayonnaise of halibut, stewed pigeons, and French pancakes or eggs on spinach, cold beef with mixed salad, orange soufflé, and cheese cakes. For summer, fish salad, French beans à la maitre d'hôtel, roast lamb, and compote of cherries with custard sauce; for fall, grilled mackerel, minced chicken with spinach, bread-crumble pudding, and stewed prunes; and for winter, stuffed fillets of fish, Russian steaks, apple charlotte, and coffee eclairs.

before. In this, the brunchers improved on the medieval courtiers who ran from one meal to the next. A meal of absolute leisure, brunch obliterated the need for form and attention to hours, trumpeting the freedom of the brunchers from the tyrannies of the workday. It was an excellent means of marking the dandy as a creature entirely divorced from the middle class, and only when it was taken up as a weekend form, largely in the United States in the 1930s and 1940s, did it transform itself into the respite from the workweek that we know it as today.

### Lunch in America

Though the process through which lunch developed in America closely mirrored that of England, the timetable was much slower, as the country moved more gradually from rural to urban economies. The working classes began eating a quick meal known as lunch—usually a brown-bag affair brought from home—in the nineteenth century, but the practice of referring to the midday meal as dinner persisted in many rural areas through the 1940s. The development of the upper-class lunch also occurred

much later. Harvey A. Levenstein in *Revolution at the Table* places that transition in the 1880s and attributes the later dinner hour not only to fashion, but also to the American work ethic. Even men who did not work, he claims, liked to be seen as busy during working hours, and so were loathe to sit down to dinner in daylight. Particularly, but not exclusively, among the privileged, “nooning” persisted in America through the nineteenth century as a term referring to a light midday meal taken at leisure, often in less than formal circumstances.

By the early years of the new century, the ladies’ luncheon was common, and home-based luncheon clubs for ladies were proliferating. But since many men of the middle and upper classes ate their midday meal at home, luncheon in America had much less of a gendered character than the British variety. Through the twentieth century, as children came home from school to eat lunch, the meal was made to bear the weight of America’s great nutritional edicts, so that homemade meals and the women who cooked them shouldered the responsibility for the emotional, physical, and intellectual well-being of the nation’s children. Women of leisure took their midday sustenance in public restaurants, marking their distance from the labor of the home by combining lunching or luncheon, as they termed it, with shopping and other wealth-driven pursuits of pleasure.

In the public world of work, lunch in America was driven by the nation’s speedy, progress-obsessed business culture. As Daniel Boorstin notes in *The Americans*, soon after the Civil War, the notion of the lunch counter evolved, modeled on the horrible “refreshment rooms” in railroad stations, where commuters in a hurry downed worse than mediocre food at top speed. The lunch counter, like the refreshment room, was based on the premise of moving patrons in and out quickly; the setting and the seating were less than luxurious, and the food was served up extremely quickly, encouraging rapid turnover (a business practice that Ray Kroc, the entrepreneur behind McDonald’s, elevated to an American art form). Unsurprisingly, innovation- and efficiency-driven Americans also developed the concept of the lunch box, complete with divisions for various types of food and eating implements, for which patents were applied in 1864.

In its contemporary American incarnation, lunch continues to incorporate many of the class- and gender-driven connotations of its nineteenth-century manifestations. Office workers may eat a quick lunch—brought from home or ordered from a take-out or delivery restaurant, contemporary versions of nineteenth-century food carts and chophouses—at their desks, or they may use their lunch hour, a sacred American twentieth-century institution, for leisure activities, shopping, exercising, or eating out at restaurants that devote themselves in some way to fast noontime service. People of real leisure and means eat lunches in restaurants, and the notion of the salad-eating “lady who lunches” still holds considerable currency. Though the notion of the business lunch, an-

other midcentury American institution, has declined somewhat (and the legendary three-martini lunch has more or less disappeared, as a faster, meaner working world has evolved), lunch remains an important public meal for executives, who often use it as an opportunity for doing business, just as eighteenth- and nineteenth-century “Change Alley” businessmen once made deals in the coffeehouses of London. Business luncheons are more formal affairs, held for a larger number of people, and often involving a speaker. The term “luncheon” in general now refers, in the United States, to a formal affair involving a substantial number of participants, though in Britain it may also refer to a relatively formal repast for one person or a small group of people. For children, lunch is still seen as a particularly important source of nutrition, as the hot lunch programs in the schools attest, but as women have moved out of the home and into the workplace, the responsibility for this all-important feeding now rests with the schools and the public domain. Perhaps most tellingly, in the go-go American business environment of the early twenty-first century, the most important lunch is the one that is not eaten: As businesspeople seek to mark themselves as serious, driven, busy, they have come to see lunch as a sign of indulgence, even of weakness. Like their nineteenth-century London counterparts, ambitious workers often scorn lunch as a meal reserved for the weak, the slow, the unambitious, and the overly leisured. The best kind of lunch for the upwardly mobile entrepreneur is the one he or she has forgotten to eat.

Gwen Hyman

## LUTEIN AND LYCOPENE. See Antioxidants.

**LUXURY.** Luxury means spending more than one needs to, and, in the view of some who concern themselves with the matter, more than one ought to, on comforts and pleasures. Since eating and drinking are (to most people) pleasures, luxury may take the form of lavish spending on eating and drinking, which is the form relevant to this encyclopedia.

Consider the possibilities. You can eat more than would be necessary to stay alive and healthy. You can drink more wine than is consistent with sobriety. You can choose foods and drinks for their flavor, their appearance, their rarity, their cost, their reputation, or their brand name, rather than because they are handy and nourishing. You can also make choices of dining companions and of ambience that others consider luxurious. If you entertain friends in a Michelin three-star restaurant, you and your guests are probably doing all these things. With a focus on different individual aspects of your pursuit of pleasure, you may thus earn specialized epithets such as glutton, gourmand, gastronome, connoisseur of fine wine, bon vivant. All of these, along with the nonfood pleasures that you enjoy before and after your visit to the restaurant, are subsumed in the general term “luxury.”

Can we manage without it? *Le superflu, chose si nécessaire*: “The superfluous, a very necessary thing” is the paradoxical definition with which Voltaire approaches the topic of luxury in *Le Mondain*, a poem published in 1736. Whether or not luxury is necessary to individuals, we may still see it as playing a crucial role in human society, making the distinction between haves and have

nots, identifying social classes, setting targets for the upwardly mobile.

At any rate, luxury exists in most cultures in which some people have superfluous wealth, power, or leisure to expend on its pursuit. In ancient Greece, even the Spartans (who were proverbial for their frugal way of life) found that some fellow citizens brought better game and finer delicacies to the communal meal than others. In the twentieth century, even among the Russian Communists there was a distinction between the *Nomenklatura*, who could afford—and were authorized—to buy luxury imported produce, and the others, who could not. It seems that to bring full satisfaction to those who practice it, luxury must not be shared too widely. Thus the list of luxuries changes continually. In the early twentieth century, fresh fruits that were not in season locally, hothouse peaches, for example, were costly luxuries, available to few. Thanks to refrigeration, air freight, and cheap gasoline, fresh exotic fruit is now no luxury—but the number of food luxuries, costly products that only some people can afford, is somehow no smaller than it was before.

The practices of luxury extend worldwide. In China, there have been costly, exotic luxury foods for more than two millennia. Beginning with the Emperor and the Court, there have been people who have spent lavishly on fine foods, enjoying banquets that might number hundreds of dishes. In India and Southeast Asia, too, it is possible to read descriptions of luxury feasts and entertainments dating back nearly two thousand years. In all these countries, there have been many people who could afford none of this. Thus the necessary contrast has existed between those who want and those who command luxury. Throughout the world, there have been philosophers and hermits who have consciously renounced the pursuit of luxury in favor of meditation; among them was the Buddha, who lived in India in the 6th century B.C.E. and whose life and teaching have influenced the whole region deeply. However, Buddhism and the other ascetic traditions stopped short of criticizing those who chose to live a life of luxury. To the Buddha himself this statement is attributed: “I do not despise sensuality: I know that is what this world is. I also know it to be transitory; therefore it does not seduce my mind” (Āśvaghoṣa, *Buddhacarita* 4.85). Thus his renunciation of luxury was a personal matter; it was not enjoined on all. In this sense, in traditional southern and eastern Asia, the pleasures of luxury were not a problem: simply, some people abstained.

The great Near Eastern civilizations, Sumerian, Babylonian, Assyrian, Egyptian (fourth to first millennia B.C.E.), as they grew in wealth, grew also in their appetite for luxury. Of the Persian Empire (sixth to fourth centuries B.C.E.), which swallowed up all of these, it was said that the best foods and luxuries, and even the best drinking water, were brought from every province to the Persian king’s table. Classical Greek travelers and historians reported with awe on the vast quantities of fine produce (four hundred fattened geese and thirty pounds of anise are

just two items in a very long list) that were supplied every day to the Persian court for the so-called “King’s Dinner.” At the courts of the Hellenistic kingdoms of the Near East, ruled by Greek monarchs in the third to first centuries B.C.E., lavish and costly banquets followed the patterns already established by the Persians. The biblical legends of King Solomon’s wealthy court and of Belshazzar’s feast are inspired by Persian and Hellenistic royal feasting.

Rome’s conquests in the East, particularly in Anatolia (modern Turkey) in the second and first centuries B.C.E., brought the wealth and skills that enabled Rome to enjoy luxury on an imperial scale. The Roman general Lucullus, who served in Anatolia, is proverbial for his luxurious lifestyle: one may speak still of a “Lucullan” feast that offers the finest food and entertainment at astronomical cost. Several of the Roman emperors (first to fifth centuries C.E.), unmatched in wealth and power, fully demonstrated a capacity for luxury and gluttony. Among these emperors, Claudius (ruled 41–54 C.E.) is famous for his practice of vomiting after a big dinner to make room for another. Arabs and Byzantines continued these Roman traditions. At the marriage of the emperor Maurice, in 582, “the city celebrated for seven days and was garlanded with silver: deep platters, basins, goblets, bowls, plates and baskets. Roman wealth was spent; a luxury of golden display, the secret riches of the imperial household, formed a theatre for all who wished to feast upon visions” (Theophylact Simocatta, *History*, Book 1, section 10). There are equally breathtaking anecdotes of luxury from late medieval, Renaissance, and modern European royal courts.

The Western literary tradition of sensuous description and lavish praise for the pleasures of gastronomy and luxury has been paralleled, for more than two thousand years, by an opposing tradition urging renunciation of luxury and of the wealth that pays for it. This tradition may be traced to Greek philosophers, including Plato (c. 428–348 B.C.E.) and his contemporary Diogenes the Cynic. The pronouncement of Jesus, “It is easier for a camel to go through the eye of a needle, than for a rich man to enter into the kingdom of God” (Matthew 19:24.10) foreshadows the early Christian thinkers’ fierce criticism of the usages of luxury. Such philosophers and religious teachers were reflecting popular views and also helping to shape them. Many people, ancient and modern, have believed that overspending on food, wine, entertainment, and other luxuries is morally wrong. These views have influenced government policies. Some Greek and Roman governments imposed direct restrictions on luxury spending or legislated to cap the prices charged for fashionable products. For example, in 89 B.C.E. the Censors at Rome decreed that Greek wine should not be sold at more than one copper per gallon; a few years later, Julius Caesar (it was said) authorized officials to enter private dining rooms to confiscate dishes whose ingredients contravened the antiluxury laws. Many modern govern-

A luxurious dinner was used as tool for teaching humility and tolerance in the 1987 movie *Babette's Feast*. The story on which this film was based was a critical attack on a puritanical religious movement in Denmark called the Holy Danes. © THE KOBAL COLLECTION/BETZER-PANORAMA FILM/DANISH FILM INSTITUTE.

ments impose differential taxes on luxury purchases. In France, for example, sales tax on fast food is levied at the reduced rate for “essentials” of 5.5 percent while on restaurant meals it is levied at the standard 19.6 percent.

Those who oppose luxury tend to complain that the businesslike satisfaction of hunger, which ought to be the purpose of food and drink, is progressively overshadowed by the pleasurable satisfaction of the senses. To satisfy the sense of taste is natural enough, but it is wrong to put flavor above nourishment in one's selection of food. The same applies to the sense of smell, and are we distracted from the proper business of the meal by scents and perfumes around us? As for the sense of sound, serious conversation is quite appropriate, if only conversation were always serious and never seductive. And must the senses of sound and sight be distracted by artists employed to dance and make music at a meal? Finally, the sense of touch: must these entertainers also mix with the guests and seduce them to promiscuous sexual pleasures? Thus, at some times and in some places, luxurious meals have turned into orgies. All of this comprises “luxury,” a term that in Christian moral thinking came to be characterized as a sin. In the canonical list of mortal sins as

catalogued by Pope Gregory in the sixth century, five sins are subsumed under Pride, leaving two, gluttony and lust, to belong to the classification of Luxuria, or sins of the flesh. These Seven Deadly Sins have been a recurrent theme of art and literature ever since, woven in the mid-twentieth century into Anthony Powell's novel sequence *A Dance to the Music of Time* (*A Buyer's Market* [1952] and *The Kindly Ones* [1962]).

Examples in this article are taken from many cultures at many periods, to show how widespread is the appreciation of luxury in food and dining. In each case, therefore, the date and place are specified.

### Luxury in Detail

The simplest characterizations of gastronomic luxury are those that focus on the quantity of food and wine and on the convivial pleasures that surround them. In the *Odyssey*, one of the two early Greek epics (c. 700 B.C.E.), the hero Odysseus, addressing his host Alcinous on the magical island of Scherie, sets out what later Greek readers considered to be the quintessence of ancient *tryphē* (Greek for luxury): “I believe there is no more delightful pleasure than when there is happiness among all the people;

when feasters in the house, sitting in rows, can listen to a singer, while beside them tables are full of bread and meat, and a waiter brings wine from brimming bowls and fills their cups: this seems to me in my heart to be the best of all." Such descriptions can be found in oral literature of other times and places. Modern Americans, if recommending a barbecue, are likely to paint a similar picture, and to emphasize, like Odysseus, the quantity of meat available.

If tastes become more sophisticated, one will find that emphasis is placed on the quality rather than the quantity of food. This leaves room either for encyclopedic listing or for mouth-watering details.

The wine will perhaps be of varied kinds; Julius Caesar (100–44 B.C.E.) made his gastronomic mark by being the first politician in Rome to serve four wines in sequence at his public banquets. Or it will be from a good vineyard: the vogue of Chateau Haut-Brion, still a noted name among the Bordeaux vineyards, can be dated from the April 1663 dinner at which the London diarist Samuel Pepys "drank a sort of French wine called Ho Bryen that hath a good and most particular taste I never met with." Or it will be from a renowned region: the luxury banquet laid out in the famous tomb of King Tutankhamen of Egypt (died 1352 B.C.E.), intended for the monarch to enjoy in the afterlife, included a gourmet selection of wines inscribed with names of wine districts—appellations, one may call them—in the Nile Valley, the Nile Delta, and the Oases. Or it will be a well-aged vintage wine: in the fictional Dinner of Trimalchio, an episode in Petronius's novel *Satyricon* (Italy, first century C.E.), the boastful host presents a wine labeled with a truly great vintage, the consulship of Opimius in 121 B.C.E., and spoils the effect by adding, "I didn't serve such good stuff yesterday, and my guests then were much better class." Or it will be of a special style, like the so-called East Indian Madeira favored in eighteenth-century England: loaded in casks at the Portuguese island of Madeira, this wine took the long sea journey to the East Indies (modern Indonesia) and back again to Europe, crossing the equator ten times, rapidly developing a toasty maturity, and just as rapidly increasing its price. Or, if nothing else, it will be expensive: witness the strange early-twenty-first century vogue for Beaujolais Nouveau, harvested, vinified, and bottled in indecent haste. Wines and liqueurs that claim to belong to the luxury class may sometimes be as boastful as Trimalchio. The sweet wine of Tokay, in Hungary, is labeled in Latin *Vinum regum—rex vinorum* (the wine of kings—the king of wines). Bénédicte, a commercial liqueur from Fécamp in northern France, carries the dedication *D.O.M.* (to God, best and greatest) on every bottle.

The food will be notable in various similar ways. The meat may perhaps be that of a suckling animal, suckling-pig or baby lamb or kid; these are always expensive, because economic sense dictates slaughtering animals when full-grown. Or it may be game, from wild hare to wild

boar to grouse. In many cultures, game reflects glamour on a male host by implying that he is the huntsman; in others, including the modern West, serving boar or venison is simply a sign that serious money has been spent. As far back as the Assyrian and Persian empires, the wealthy have kept private hunting parks stocked with "wild" animals such as boar and deer; for example, thirty gazelles were supplied each day to the Persian King's Dinner mentioned above. Or the food may be taken at the precise time of year when it is known to be at its best, its tenderest, or its most flavorful; Archestratus, Europe's first gastronomic writer, insists on this point continually in his instructions for selecting Mediterranean fish. Like an appellation wine, the food may come from the very region where it is said to reach its peak of quality or from the producer who has the best reputation; this emphasis found fashion in restaurant menus in the United States in the early twenty-first century. It may be of very distant origin—which in earlier times would mean that it had necessarily made a slow voyage across dangerous seas, had passed through the hands of many traders, and would fetch a vast price at journey's end. This helps to explain certain strange and lavish uses of spices: true camphor (from Borneo) in medieval Chinese tea, nutmeg and cloves (from eastern Indonesia) in modern European cakes and puddings, myrrh (from southern Arabia) in classical Roman spiced wine, cinnamon in medieval Byzantine porridge. Cinnamon, which came to early Europe from Southeast Asia across the stormy Indian Ocean, fetched three times the price of gold.

Above such tastes as these lie the higher levels of luxury, those at which a host will pay fabulous prices to make the desired statement. Notice in the examples that follow, and in some of those already given, that the high price and reputation of the food and wine matter more than their effect on the taste buds. The visual effect of the display of wealth in tableware, decoration, service, and entertainment matters more than the (often minimal) contribution of these things to the participants' pleasure.

At these levels the wine will be of the highest reputation and of the most expensive vintage. "What kind of champagne is it?" "I'm afraid to look." "Suffering Pete—Bollinger 1911," said Guy Bolton to P. G. Wodehouse (New York, 1920s) in awed contemplation of a luxury buffet, ordered in their name, that they could not pay for (Bolton and Wodehouse, *Bring on the Girls*, chapter 5, section 6). The food must also be at the top of its class. It may be perennially rare, as is caviar (it will become rarer each year). It may be costly to produce, as hothouse peaches used to be and as foie gras still is. Foie gras and caviar are not bad, but are they really a hundred times as good as pork liver and cod roe? It is easy to name other foods that are neither as tasty nor as nourishing as their price might lead one to suppose. The ordinary eater can do little with truffles, yet their rarity and reputation ensure that the price fetched by the truffles of Périgord and

Tuscany remains extremely high. Bird's nest soup is said to be almost tasteless, yet the difficulty of obtaining it and its reputation ensure that its price is still fabulously high in China. There have through the centuries been many delicacies whose price owed more to fashion than to flavor and food value. Rome's second emperor, Tiberius (ruled 14–37 C.E.), considered legislating when the market price of red mullet, in response to fashion, rose to ten thousand sesterii each. (Note that it was Tiberius on one occasion who demanded luxury of a non-gastronomic kind by insisting, when accepting an invitation to dinner, that the waitresses be nude.) Three of this emperor's successors—Caligula (37–41), Vitellius (69), and Elagabalus (218–222)—were famed for their use of ridiculously costly ingredients. Vitellius's triumph (shortly before his assassination) was the recipe "Shield of Minerva," his personal invention. It included parrot-wrasse livers, pheasant and peacock brains, flamingoes' tongues, and the milt of moray eels, all these supplies specially fetched for him by Roman naval commanders from both ends of the Mediterranean and even beyond.

Once-exotic foods are available across the world; spices that were once fabulously costly are ridiculously cheap; philosophers and religious thinkers have ceased to decry luxury. Luxury has a past; the difficult question is whether luxury has a future.

**MACROBIOTIC FOOD.** Macrobiotics is a way of eating and living in accordance with the natural order of the universe. This simple way of life has been practiced for thousands of years, originating with the ancient Far Eastern theory of yin and yang energies, a never-ending continuum where opposites change into one another to complement, balance, and form a union; for example, the sun (yang) and moon (yin), night (yin) and day (yang); summer and spring (yang), winter and fall (yin). All things on earth are created and held in balance by these two complementary forces, a fundamental understanding that governs the whole universe. The human body is included in the universal cycle of the endless harmonious motion of change. All the major organs and functions within the body have a cycle of yin and yang movement. For example, when we inhale (yin), we must also exhale (yang); the body needs both rest (yin) and activity (yang). Foods and liquids restore and maintain the body. Therefore, the macrobiotic way of living and eating is about understanding how to live simply and choose and prepare food in conjunction with the natural order of the universe, creating physical, mental, and spiritual well-being. The sidebar at right lists yin and yang characteristics.

### The History and Development of Macrobiotics

The word “macrobiotics” comes from the Greek *makros* meaning ‘large’, ‘a great’ and *bios* meaning ‘life’. Hippocrates first used the term in the fifth century B.C.E. in his essay “Air, Water, Places,” about a group of people who lived long and healthy lives. Even to this day, his famous quote, “Let food be thy medicine and medicine thy food,” continues to be acknowledged and respected. Hippocrates emphasized that life itself depends upon what foods are consumed and how they are prepared. He suggested that healing takes place when foods are eaten in their most natural form.

While Hippocrates coined the term, macrobiotics was practiced hundreds of years earlier in the Far East. Around 500 B.C.E. one of the world’s oldest medical books was written, *The Yellow Emperor’s Classic of Internal Medicine*, a compilation of the medical wisdom of ancient China. The book states that people who lived in harmony according to the laws of nature, balancing yin and yang energies, lived long and healthy lives. This wisdom is be-

lieved to go back even several thousand years earlier. “Macrobiotics” became a common term used in early Western literature, including the Bible, to describe patriarchs such as Abraham as “Macrobiotic people.” In 1797 Dr. Christopher W. Hufeland, a German philosopher and physician, challenged medical practices by becoming a macrobiotic spokesman in Europe. His publication of *Macrobiotics or the Art of Prolonging Life* warned against popular foods like meat as well as foods containing refined sugars in favor of a simple vegetable and grain diet.

The development of macrobiotics as it is known today is credited to George Ohsawa (1893–1966; formerly Yukikazu Sakurazawa), who overcame tuberculosis in 1909 by rejecting Western medical treatment in favor of a simple diet of whole cooked grains such as brown rice, earth and sea vegetables, beans, seeds and nuts, and miso soup. The source of the information that relieved his illness was *A Method for Nourishing Life Through Food: A Unique Chemical Food-Nourishment Theory of Body and Mind*, written by Japan’s Sagen Ishizuka in 1897. Ishizuka’s vision consisted of eliminating a diet of meat, dairy products, potatoes, eggs, white bread, simple sugars, and the other highly refined foods of modern civilization. He contended that eating this way goes against the natural order of the universe and humans’ immediate environment, thus causing people to lose their physical, psychological, and spiritual

### CHARACTERISTICS OF YIN AND YANG

#### ***Yin***

Colder  
Darker  
Longer  
Larger  
Softer  
More inactive, slower  
More expansive, hollow

#### ***Yang***

Hotter  
Brighter  
Shorter  
Smaller  
Harder  
More active, faster  
More contractive, solid

<sup>1</sup> Brie, Roquefort, and several other salted cheeses that have aged for a long time are classified as yang rather than yin.

<sup>2</sup> Soft drinks, candy, pastries, desserts, and other items containing these sweeteners should also be avoided.

vitality and harmony. According to Ishizuka, the ability to experience the highest levels of spirituality is controlled by food. He emphasized that the great sages and saints all lived on whole cooked grains and vegetables cooked with salt. Ishizuka was also concerned with the way eating patterns determined how families and societies functioned. His philosophy and scientific studies echo the macrobiotic way of living and eating in the early twenty-first century. He emphasized balancing Na-dominance (sodium) and K-dominance (potassium) in foods, which is also known as the acid-alkaline balance. Ohsawa amended Ishizuka's theory by imposing yin and yang forces onto the acid-alkaline balance, contending that these energies make up the mystery of life. Ishizuka's work sparked Ohsawa's passion to study, write, and extend his own version of macrobiotic practice and teachings to American, Asia, and Europe.

### Macrobiotic Foods

A macrobiotic diet is defined as eating in balance between extreme yin and yang energies. For example, animal meat is considered an extreme yang food and creates natural strong cravings for extreme yin foods, such as refined sugar in cookies and cakes. Extreme foods create sickness and are the body's warning that there is an imbalance. The imbalance causes the blood to become too acidic, creating an environment in which diseases can thrive. Human organs, especially the kidneys, need to work harder to buffer the acids and maintain a normal pH alkaline blood condition of 7.35–7.45. Scientific studies have shown how a sustained acidic condition can cause normal cells to change to cancer cells. (The sidebar below illustrates foods in relation to acid and alkaline.) If extreme foods continue to be consumed, the body starts accumulating and storing toxins in the form of mucus, fats, cysts, and tumors.

To avoid these undesirable conditions, the consumption of whole, unprocessed foods grown without pesticides and other chemicals is recommended. These consist of earth and sea vegetables, whole cooked grains such as brown rice and millet, bean products, seitan (a

wheat-based food), nuts, seeds, and occasionally fish. Seasonings and condiments are used to add nutritional value and to enhance flavor. These include miso, made from soybeans and sea salt commonly flavored with fermented barley or brown rice, which strengthens the blood; *umeboshi*, a salty plum that neutralizes extreme foods and conditions; sea vegetable flakes, which are high in minerals such as *dulse* and nori; *tekka*, a powder made from *hatcho* miso, sesame oil, burdock, lotus root, carrots, and gingerroot that is simmered for several hours and gives strength; *gomoshio*, a mixture of sesame seeds and sea salt high in calcium; and shoyu soy sauce to help with digestion. *Kuzu*, a white starch made from the deep root of a wild vine that helps digestion, thickens sauces. These condiments and seasonings have a variety of medicinal uses and can also maintain normal levels of blood alkaline. Eating these foods, seasonings, and condiments balances the body without causing cravings for extreme foods; thus, the transition of foods from yin to yang and vice versa is smoother, thereby creating internal balance and promoting health.

In a temperate climate, macrobiotic foods do not include nightshade vegetables such as tomatoes, potatoes, peppers, and eggplant. These foods are high in alkaloid content and contrary to the healing process. By eating nonpollutant food, the body has a chance to clean out stored chemicals, increase nutrient absorption, and improve health.

### Cooking Techniques

Cooking processes also have a yin and yang quality. For example, cooking meals, such as beans, longer involves more heat, which indicates yang energy, and this way of cooking complements cooler seasons such as winter, which is yin. In contrast, lighter meals, such as salads, and quicker cooking methods are yin, which complements warmer seasons such as summer, which is yang. This style of cooking and eating promotes remaining in balance with the changing seasons, supporting the natural order of the universe.

A gas stove is recommended for cooking macrobiotic foods because the heat comes from natural energy. Also urged are cooking with natural spring water when needed and using stainless steel, glass, cast iron, and porcelain cookware to keep the food away from possible contamination that may occur with aluminum and synthetic coatings. Ideally, foods are locally grown in season to promote internal balance and harmony with the environment.

### Food and Behavior

There is also a cause and effect relationship between food and behavior. For example, eating mostly extreme yang foods usually leads to irritability and anger, while eating mostly extreme yin foods usually leads to depression and reduced energy; however, soon after eating extreme yin foods, such behavior as explosive anger has been noted.

#### ACID AND ALKALINE IN FOODS

##### *Too much alkaline*

Refined salt

##### *Too much acid*

Meat, eggs, fruits, sugars

##### *Lower alkaline*

Miso/shoyu  
soy sauce

##### *More Balanced*

Sea/land vegetables

##### *Lower acid*

Grains, beans

Eating foods that are balanced with yin and yang energies without extremes maintains a normal alkaline blood level and leads to vitality and a peaceful, more comfortable state of mind. Table 1 illustrates foods associated with certain behaviors and moods.

**TABLE 1**

<b>Yin and Yang foods associated with behaviors</b>		
	<b>Foods</b>	<b>Behaviors</b>
Extreme Yang	Refined salt	Aggressive
	Meats	Overactive
	Poultry	Angry, irritable
	Fish (blue and red skin)	Attacking, intolerant
	Hard salty cheese	Self pride
Balanced		Voice too loud, tense
		Tense muscles
		Dry skin
	Grains	Assertive
	Vegetables	Active
	Sea vegetables	Content, patient
	Miso	Positive outlook
	Beans	Satisfied with life
Extreme Yin	Seeds	Voice pleasant
	Nuts	Relaxed muscles
		Smooth, clear skin
	Sugar	Passive
	Honey	Overly relaxed
	Molasses	Depressed, sad
	Coffee, caffeine	Negative, retreating
	Milk	Self-pity
	Ice cream	Voice too soft, timid
	Yogurt	Loose muscles
		Moist skin

The standard macrobiotic diet consists of 30 to 50 percent whole cooked grains and whole grain products, such as sourdough bread and pasta (including *udon* noodles made with wheat flour, brown rice, and sea salt and *soba* noodles made from buckwheat flour); 20 to 30 percent locally grown organic vegetables; 5 to 10 percent beans such as adzuki and lentil (including tofu made from soybeans, *nigari*, and water and tempeh made from split soybeans, vinegar, and water); 5 to 10 percent soups, including miso and vegetable; and 5 percent condiments, such as *umeboshi* plum, *gomashio*, and sea vegetables, including *wakame* and *kombu*. Macrobiotic foods are high in complex carbohydrates, fiber, vitamins, and minerals that provide the balance of proper nutrition that the body needs.

A very basic balanced macrobiotic meal may consist of: one cup of miso soup made with onions, carrots, and sea vegetables such as *wakame*; one cup of whole cooked grains, such as brown rice seasoned with a pinch of sea salt; one-quarter cup of cooked beans, such as adzuki mixed with a small amount of the sea vegetable *kombu* and a sweet vegetable such as butternut squash seasoned with shoyu soy sauce; one cup of cooked green and yel-

low root and leafy vegetables; a pickled vegetable; and a garden salad. Fish can be eaten occasionally along with soy products such as tofu and tempeh to substitute for beans to provide protein. For dessert, a recommended dish may be couscous cooked with apple juice and apples. Also used for sweeteners are barley malt and brown rice syrup. In addition, *kukicha bancha* tea, which has a pleasing taste, is used as a daily beverage that has virtually no caffeine, alkalizes the blood, has a beneficial effect on digestion, and relieves fatigue.

Recommended macrobiotic foods and their portions vary according to a person's physical and mental condition, climate, and age. For example, someone with a slower metabolism may benefit from eating fewer grains and more vegetables. Macrobiotic counselors throughout the United States help people adjust the diet to their specific needs.

### The Spread of Macrobiotics

Macrobiotics owes much of its contemporary popularity to George Ohsawa and his wife, Lima. His students Aveline and Michio Kushi developed the Kushi Institute in Brookline, Massachusetts, which helped spread macrobiotic teachings and practices in the eastern United States. Cornelia and Herman Aihara, also Ohsawa's students, developed the study and practice of macrobiotics in the western United States. Macrobiotic food may be found in health-food stores, and macrobiotic cookbooks are available there and in major bookstores throughout the United States. In the early twenty-first century, there are over five hundred macrobiotic centers throughout the United States whose advocates stress the advantages of this way of eating and living. The more common benefits experienced are increased vitality, better sleep, a stronger immune system, reduced fatigue, and improved memory. There are also scientific and medical studies which indicate that following a macrobiotic diet can prevent or relieve cancer and other terminal illnesses. These benefits are said to result from a body cleared of chemicals and toxins. Practicing the macrobiotic way of life moves beyond physical health to also revitalize the true nature of mental and spiritual well-being.

**MAGIC.** The English term “magic” (*magie* in French, *Magie* in German, and *magija* in Russian) comes from the Greek *magikos*, a term that referred to a class of priests in ancient Persia and Greece. Later the word was taken over by Christianity and applied to the kings (“magi”) who traveled to pay their respects to the infant Jesus. It was not until the Middle Ages that the word “magic” took on negative connotations. In modern times, magic refers to witchcraft, sorcery, and the casting of spells. Magic is also part of rites and ceremonies that are connected with the belief in a supernatural influence on nature, animals, and human beings. The field of ethnology uses the term “magic” very widely, but the meaning of the term is not always clear. Witchcraft was opposed by official religions from ancient times, as, for example, the Indian “Laws of Manu” (sixth to fifth centuries B.C.E.) and the Roman “Laws of 12 Tables” (mid-fifth century B.C.E.). The position of Christianity was shown in the Codex of the Emperor Justinian (529). Among the East Slavs, witchcraft was considered a superstition and a relic of paganism and therefore a sin. There is a tradition of identifying magic with witchcraft and distinguishing “white magic” from “black magic.” Around the turn of the twentieth century, A. Lemann and others associated magic with sorcery. Lemann formulated the most popular definition of magic: “Magic or witchcraft is every action provoked by superstitions.” B. Malinovsky wrote that magic was from ancient times the province of specialists and that witchcraft or healing was the first profession.

The connection of magic with religion and religious rites has also been interpreted in many ways. Sir James George Frazer thought that magic was founded on men and women’s belief in their own potential to influence nature; this stands in contrast to the concept of religion, which is built on a belief in supernatural beings (gods, spirits, ghosts) that control natural phenomena. Other theories assert that religion is inseparably linked with magic. S. A. Tokarev gave a description of religious rites

that can be classified as magic rites, depending on their form and function. The division of magic by form proceeds from the psychological mechanism behind the use of magic forces, including establishing contact, initial (beginning), imitative magic, apotropaic magic (to avert evil), cleansing, and verbal magic. The division of magic according to function is linked to real-world or practical roots of magical beliefs: for example, medical magic is connected with folk medicine, love magic is connected with courting, trade magic is associated with hunting techniques, and agrarian magic is linked to primitive agronomics.

Food is associated with almost every kind of magic. Magic rites connected with food production, processing, and presentation reflected ancient beliefs and motifs that had lost their primary mythological meanings over time and had become inalienable elements of different religions. For example, it is no coincidence that figures from Slavic mythology were identified with Christian saints, such as Peroun, the god of rain, or in India Pardjanja, Pirva (Hettish), Perkons (Lettish), with St. Eliash; Veles, the god of cattle and wealth, with St. Vlasij; and Yarila, the god of fertility, with St. George. The roles of these figures are reflected in folklore, and especially in demonology. Traces of this type of folklore can still be found in modern times. For example, the Orthodox Church does not deny the presence of evil and other evil spirits in everyday life, but it does not support the spreading of superstitions among its followers. Nevertheless, such beliefs still exist and are reflected in ceremonies surrounding food production.

Beyond its main role of satisfying one of the vital requirements of the human organism, food plays a large symbolic role in every culture. Group meals and specific types of food are obligatory components of any festivity or event in most cultures. Depending on the societal and cultural context, food can be viewed as ritualistic, festive, sacred, funereal, prestigious, and non-prestigious. For example, many sacred rites are connected with the production of bread. It was common in many cultures to bless and to pray during bread baking and to put a cross on the bread before it was eaten. In Georgian beliefs, bread protected a child from evil spirits. Depending on the situation, a different number of loaves (accounts tell of anywhere from three to twenty-nine) could be used during magic actions. In Armenia, in order to protect her child from evil, a mother collected flour from seven families, baked bread (*lavash* in Armenian) in the shape of human being, put it under the pillow of the child, and on a certain day buried the bread. If a child became ill during the first forty days of life, he or she was passed through the hole made in a large loaf of bread. In Armenia bread was also seen as a form of sustenance in the afterlife: this belief was observed in a ceremony where fresh bread was offered for the deceased. The Udmurts often used similar magic. To return her child to health a mother baked bread three times in a day: the first time

*Hexefuss* (witch track) on a Hubbard squash. The mark, which resembles a goosefoot, was viewed as an omen of bad luck or impending disaster among the Pennsylvania Dutch. It appears on both fruit and vegetables and is thought to be caused by a fungus, although folk belief explains it otherwise. PHOTO BY WILLIAM WOYS WEAVER.

she baked five small loaves; the second time she baked seven loaves; and the third time, nine loaves. To strengthen the magic influence she formed dough on a kneading trough and hid herself from the daylight under a shawl.

In some rituals, bread was used to protect the human world from another one. Among eastern Slavs it was a custom to keep bread on the table that was in the “red” corner (red in Russia means beautiful) or iconostasis, a shelf on which icons were kept, regarded as a sacred place. Bread has upper and bottom sections; thus, turning bread over was forbidden, as it was believed that the bread could be “offended” by that act. Bread and salt were the obligatory foodstuffs involved in the Russian ritual of entering a new house. Among Russians, Ukrainians, and Belorussians (White Russians), only men could first enter a new house, with icons and bread in their arms as the main symbols of a new living space. They might also carry a pot of porridge or kneading trough with dough, which symbolized prosperity, abundance, and fertility. Over time these items were supplemented with such cultural symbols as poppy seeds, thistle, burdock, garlic, and religious texts, which were supposed to protect a house from evil spirits and witches. In northern Russia, peasants invited friends and neighbors to enter a new home and treated them to a good meal to protect the house from undesirable people.

Magic and magical acts, such as the casting of spells, have traditionally been connected with health. Thus, many rites included actions and language that were supposed to help maintain or attain a state of good health. Rites such as these stood in opposition to illness, death, and misfortune. The main elements of water, fire, earth, plants, and animals were considered symbols of health and played a prominent role in different magical ceremonies.

World folklore provides evidence of a close correlation between the universe and human beings. According to the cosmological beliefs of the people of the Caucasian region, there is a Tree of Life at the back of beyond that connects with three vertical levels: a sky (the upper world), Earth (the middle world), and an underground kingdom (the lower world). The upper world is populated with gods, deities, birds, and fantastic beings. Earth is populated with people, animals, and plants, and the underground kingdom is a world of the dead, as well as devils, dragons, and deep waters. Fantastic horses, eagles, devils, dragons, animals, birds, and others beings were seen as means of communication among different levels or worlds. For example, in Caucasian-Iberian mythology there is an image of a deer with a large antler that holds up or supports the upper world.

Baking rituals in different countries reflected some of the beliefs about communication between the lower world,

the human (middle) world, and the upper world. In one ritual, the Belorussians baked three pies as symbols of the three parts of the structure of the world; in modern times, these pies have taken on different religious significance. These pies can be either round, three-cornered, or oval in shape. One never cuts three-cornered and oval pies with a knife; rather, one divides them by hand into arbitrarily sized parts. Only the round pie, which in more recent times is dedicated to the Christian savior, is cut into sections with a knife in accordance with ancient rules. The final form or figure of the sliced pie is a circle divided into an eight-segment circle or *mandala*—a cosmological symbol of the universe. Thus, these three pies reflect in a symbolic form the vertical structure of mythological space.

Religious symbolism very often stems from magic practice, which supposed a transfer of symbolic qualities from one object to another. For example, eggs, rice, and pomegranates are traditional symbols of fertility and prosperity. An egg, as a symbol of life, was used for Easter festivities and also for many other ceremonies connected with food production. Russians, Ukrainians, and Belorussians prepared special pies or chicken with an egg inside for weddings. In Daghestan, women always baked fancy cakes with eggs inside in the springtime as a symbol of the revival of life. There is a tradition among the Crimean Karaims (Karais) of putting magic patterns of sun, moon, stars, and fish on Easter bread, which is made in the form of a sun.

Magic stemming from the upper world was thought to provide a possibility of survival in difficult situations, such as finding food when one is faced with starvation. An example is the fairy tale “Jack and the Beanstalk,” which tells a story of the magical properties of three fava beans (*Vicia faba*). A. C. Andrews pointed out an abundance of bean stories and superstitions and attempted to explain these as being an adjunct of an original Indo-European totemism. He drew almost exclusively on classical sources from the Greeks, Romans, and other closely related Mediterranean peoples.

The earliest and most abundant mentions of bean superstitions came from Greek city-states. Literature from ancient Rome contains similar references. R. Rowlett and J. Mori analyzed the work of their predecessors, including A. C. Andrews, and discovered that “favistic” folktales about beans were not always connected with favism (1971, pp. 98–100).

The motif of communication with the upper world can be seen in the calendar ceremonies of eastern Slavs, who bake special bread with forty stripes, which recall Jesus’s footsteps on the Day of Ascension (forty days after Easter). The eastern Slavs bake another type of bread—*onoochkee*—that represents the cloth wrapped around Jesus’ feet. Russian peasants put such bread in the rye field, believing that grain would provide strength. People in southern Russia baked similar bread on the fortieth day

after an individual’s death. Mourners put bread on the bench by the gate of the house, and people later ate it with honey. On that day some people ate pancakes at the nearest crossroads to prevent the deceased from returning home.

Magical food has been involved in many burial customs and rites that confirm a constant link between the living and the dead. For example, in many cultures magic rituals involved feeding deceased people, or more specifically, feeding their souls. Such symbolic actions were often performed on the stove in the home. Food was thrown about the house near the body of the deceased. Sometimes people placed food in the deceased’s mouth, such as in the traditions of the Nganasans of Taymyr, Russia. Closely associated with these rites are the ceremonies that occurred after burial, because they include the same feeding of the souls. In addition to traditional funereal meals, many religions have ceremonies on special days that involve food and the deceased. Such celebrations are popular in Latin America. Mexicans have celebrations in August and November that involve the notion of spirits enjoying the smell of food. Persians put food on houses and roofs in the middle of March to encourage prosperity in the next year. B. Propp retraced the great role of the cult of ancestors in Russian agrarian festivals. Eastern Slavs celebrate “Parents’ Saturdays” in accordance with the Orthodox calendar (*Dzjady* in White Russia) and the Japanese celebrate a Bon’ Day. Russians always put out a glass of spirits with a piece of bread on the day of a funeral and on subsequent anniversaries. It is still a rule in Ukraine to have breakfast together with the deceased at the cemetery on the next morning after the funeral and to eat bread, sweets, and cakes and drink spirits. In Russia, visiting the cemetery on the second day after Easter (*radunitsa*) and sharing a meal with the deceased also became a custom: the meal was a painted Easter egg and sweet bread that were placed in the tomb.

Eastern Slav celebrations at Shrovetide and at Christmas were both devoted to the memory of the deceased. These days were observed by the preparation of such obligatory ritual dishes as bliny (pancakes) and *kissel*, made from oat, fruits, or berries. This tradition still exists among Russians. Ukrainians have a custom of preparing compote and small sweet pies with jam at funerals.

An example of using verbal cliché with magic purpose can be found in the texts of the Apocrypha, biblical books of dubious authenticity that are excluded from the Jewish and Protestant versions of the Old Testament. Nevertheless, apart from the fasts on Fridays established by the Orthodox Church, there was a tradition of fasting on the twelve “Temporary” Fridays, or “Vow” or “Big” Fridays, that were very popular among Orthodox adherents. Fasting on Fridays was a well-known practice of the use of the apocryphal texts as amulets, which was widespread in many cultures. The main role of the Apocrypha was to protect people from different troubles but only

under the condition of fasting. Orthodox Christians kept fasts on these days to prevent unexpected misfortunes such as drought, bad harvests, infestations, and diseases.

The apocryphal Twelve Fridays were widespread in Russia in the guise of legends, spiritual verses, and tales dating from the eleventh century. Wandering (usually blind) minstrels sang the verses and advised followers to respect Fridays by "saint fasting and praying, faith and love, gentleness and humility." The verses warned that anybody who committed a breach of Fridays would be punished for generations to come.

In Russia the texts about the Twelve Fridays (as the texts "Dream of Our Lady") were also used for magical purposes and were worn on the body and used as amulets. However, such texts were not just magical; they were manifestations of piety in many provinces where they were distributed in the form of manuscript copies, apocryphas, and spiritual songs.

In the nineteenth and twentieth centuries, the texts of the Twelve Fridays could be found in many Russian provinces. They were dedicated to the main feasts of the Church calendar, and people fasted on Fridays before these holidays. Every Friday had a special grace and promised special preferences. The Twelve Fridays manuscript is still popular. People still believe that keeping fasts on these Fridays protects them against diseases and disasters.

#### MAIZE.

*This entry includes two subentries:*  
The Natural History of Maize  
Maize as a Food

#### THE NATURAL HISTORY OF MAIZE

Maize, also referred to as corn or Indian corn in the United States and Great Britain, respectively, is a cereal plant of the Gramineae family of grasses that today constitutes the most widely distributed food plant in the world. Accordingly, maize—from the Arawak *mahiz*—is grown in diverse regions and climates, from 58 degrees north latitude in Canada and Russia to 40 degrees south latitude in South America. Maize cultivation and processing are driven by the production of food and livestock feed, fermentation, and raw materials for industry.

Chestnut dibble or planting peg from Maryland, circa 1850. The top of the dibble is cut to fit the thumb. Farmers planted maize by stabbing the plowed ground with the dibble and dropping a seed into each hole. Beside the dibble are seeds of King Philip Flint Corn, a variety that emerged in New Hampshire during the 1830s. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

Given its many uses, maize is likely to be found in over 1,000 products in a well-stocked U.S. supermarket. The specifics of maize production, reproduction, cultivation, processing, and consumption—its resiliency, mutability, as well as the intractability of cultural and botanical constraints—continue to provide science with insights into the past and possible future of the species. Not surprisingly, maize is the most studied plant species on the planet.

### The Ethnobotany of Maize

Ethnobotany, the study of symbiotic relationships between human cultures and the plants on which they rely, is one of the many fields of study fueling investigations into the earliest domesticated maize and its subsequent global diffusion. Ethnobotanists, archaeologists, anthropologists, taxonomists, food and horticultural scientists, nutritionists, geneticists, biotechnicians, art historians, and many others are all trying to find answers to the numerous questions posed by the evolution and proliferation of maize. This diverse body of scientific sources provides information about the natural and cultural history of maize.

### The Quintessential Maize Plant

Experts have established that modern maize evolved from *teosinte* (God's corn), or *Zea mays* ssp. *Mexicana*, although some botanists continue to argue that it evolved from an early Mesoamerican maize variety called *Chapalote*. Even the timing of maize origins has been questioned. A review of the botanical characteristics of both maize and *teosinte* will distinguish them and provide some idea of

how maize developed into the fully domesticated cultivar it is today.

According to plant geneticist John Doebley, maize (*Zea mays* L. ssp. *mays*) and the *teosintes* (*Zea* spp.) differ profoundly in terms of vegetative characteristics and “inflorescence architecture” (1996, p. 66). That is, differences are specific to the form of the plant and its reproductive architecture, including variation in the mode of development and arrangement of the flowers or blooms along the axis of the plant.

In this instance, the distinctions are most notable in the forms of the male tassel, or spikelet, that sprouts at the summit of the maize or *teosinte* stalk, as well as in the form and development of the female inflorescence or maize ear. Despite these distinctions, Doebley acknowledges that maize and the Mexican *teosintes* are essentially variants of the same biological species. As such, they form fully fertile hybrids and cross-pollinate; the inherent differences in chromosome structure and other genetic aspects between *teosinte* and maize are no greater than those observed among the diverse races of maize (p. 66). Experiments distinguishing genes of *teosinte* from maize have been replicated in recent years through the use of molecular analysis.

The characteristic reproductive pattern of maize is a very ancient and primitive one. Maize includes both male and female reproductive characteristics and constitutes an Andropogonoid grass that bears a spike-like axis or tassel on which flowers or blooms are attached and from which pollen is dispersed; it is a self-pollinating plant that disperses pollen from the tassels to the “style” or “silk” of the maize ears (female inflorescences), where it is absorbed in the reproductive process. Whereas each tassel contains some 25 million pollen grains, each female inflorescence or maize ear contains upwards of 1,000 ovules or potential kernels. Each pollinated silk is thereby transformed into an individual kernel of maize that grows to contain a single ovule necessary for the reproduction of the plant itself. Maize leaves track the sun's light and absorb its energy; a field of maize is optimally designed for producing high yields from solar energy.

### Maize Variation and Race

There are some twenty-five “primary” races of maize found in Mesoamerica, and none of these is pure. The proliferation of hybrid variants and recent advances in bioengineered or genetically modified varieties of maize has seemingly sealed the fate of this most ancient foodstuff. In fact, the global proliferation of genetically engineered foods is poised to completely displace or replace existing strains of the primary grain crops with biologically engineered substitutes.

The evolutionary history and inherent mutability of maize are so complex that scientists continue to debate and question the taxonomic identification of all the extant races of maize in both wild and domestic contexts.

There is no agreement about the taxonomic names or numbers of races that may exist in any single world region. Since maize is so easily hybridized, the number of varieties far exceeds any other crop species on record. Botanical taxonomists have loosely grouped these varieties into some 300 races for the Western Hemisphere alone. Early textbook taxonomies, on the other hand, once identified only six races, including dent, flint, flour, sweet, pop, and waxy varieties. Of these, two dominate American commercial agriculture and include the Flint (*Zea indurata*) and Dent (*Zea indentata*) varieties. The nine major types cultivated in the United States include the Southwestern Semidents, Southwestern twelve-row, Pima-Papago, Great Plains Flints and Flours, Corn Belt Dents, Southeastern Flints, Southern Dents, Derived Southern Dents, and Northern Flints.

Of those races of maize indigenous to Mesoamerica, four main groups of maize have been identified. Their respective taxonomic classifications are based on the vegetative characteristics of the plant, characteristics of the spike or spikelet, characteristics of the cob, and the physiological, genetic, and cytological characteristics of the plants studied. These primary maize groups are (1) antique indigenous, (2) exotic pre-Columbian, (3) prehistorical mestiza, and the (4) not well-defined or modern races. To this latter category may be added the proliferation of genetically engineered strains.

The antique indigenous group consists of those races that originated in Mesoamerica with the primitive earliest races of maize. Variations within this group are thought to be evidence of multiple independent origins in diverse areas of Mesoamerica. The races specifically identified with this group include Palomero Toluqueño, Arrochico Amarillo, Chapolote, and Nal-Tel.

### Maize in the New World

The history of maize and its domestication may be traced back some 8,000 years. Maize spread across the length and breadth of the Americas, and subsequently to Europe, Africa, and Asia. Teosinte (*Zea mexicana*) has been linked with the earliest maize in Mesoamerica and was first harvested as early as 10,000 years ago.

The origins of maize begin on the Pacific slope of the modern Mexican states of Oaxaca, Tehuacán, and the Valley of Mexico. The earliest primitive corncobs discovered in Mesoamerica were obtained from specimens recovered within a cave near Oaxaca. From there maize diffused rapidly into Central America and then into South America by way of the eastern slopes of the Andes approximately 4,000 years ago. Guatemala may have served as the source or conduit for the adoption of the earliest strains of maize in Andean South America and Peru. In fact, the initial appearance of maize in Peru has been dated to 6070 B.C.E. Ecuador, Chile, and Argentina, with Andean Peru, form a likely corridor for the transmission of maize from Guatemalan sources into coastal valleys. Some nineteen races of maize from ten Latin American coun-

tries have been identified with the Classic period of 300 to 900 C.E. Six of these evidenced interactions between Mesoamerican and Peruvian societies from the most remote periods of pre-Columbian cultural development.

**New World dispersals.** Walton C. Galinat has traced the diffusion of maize into North America to a Northern Flint Pathway established by 700 C.E. in the Rio Grande valley. From there maize spread northward along both the eastern and western flanks of the Rocky Mountains, and eastward along major river courses—including those of the Arkansas, Mississippi, Platte, and Ohio Rivers—permitting its continued cultivation and dispersal eastward. By 1200 C.E., maize cultivation was established in upstate New York and New England. While the eight-rowed variety of maize was cultivated in the southeastern United States in pre-Columbian times, the Southern Dent Pathway accounts for the distributions of other varieties of maize after 1500 C.E., subsequent to Spanish contact in those regions. Ultimately, the hybrid vigor identified with the larger and more robust forms of maize can be traced back to the merging of the Northern Flint varieties with the Southern Dent varieties by U.S. farmers of the Midwest in the mid-nineteenth century. According to Galinat, this hybrid fusion can be characterized as having resulted in an “inadvertent evolutionary explosion” that ultimately transformed maize into a highly productive and important foodstuff.

### Maize in the Old World

Even before the Wampanoag Indians presented the early Plymouth colonists with maize at the first Thanksgiving celebration in 1621, enabling this early English colony in present-day Massachusetts to survive, maize had already made its way back to the Old World and was rapidly being incorporated into the agricultural economies of sixteenth- and seventeenth-century Europe and the Middle East, the Balkans, Africa, India, and Asia. In fact, according to Sylvia Johnson, as early as the mid-sixteenth century, maize had been introduced to Europe, western Asia, Africa, and China. These early Old World encounters with maize were ambivalent toward the exotic grain then known as Turkish wheat, Turkish grain, Spanish wheat, or Indian corn. In fact, negative reactions to maize in the Old World largely focused on the belief that maize was less nourishing than extant European grain products such as the wheat, barley, or oat cereals used in the production of bread and related by-products.

Despite its considerable productivity in comparison with wheat, its shorter growing season, and its considerable adaptive potential to marginal environments, maize was initially seen as a foodstuff fit only for animals or the poorest of the peasantry, who ground it up with water and ate it as a finely ground mush or porridge. This came to be known as “polenta” to the peoples of northern Italy, which has since been incorporated into European and American cuisines. Beginning in Italy, a variety of toppings and additives, including

cheese and pasta, have diversified the ingredients of this poor persons' food and transformed it into an international favorite.

In China and Southeast Asia, maize is cultivated in rotation with other, more traditional crops like rice or millet, and sequential cropping (relay cropping) strategies permit a form of multiple-cropping that overlaps the life cycles of two or more crops. These methods made possible the generation of crop surpluses in Asia beyond those originally identified with the exclusive or traditional reliance on rice as a primary cultigen. In fact, maize is being used throughout Asia to supplement more traditional crops by extending the growing season and expanding production potentials throughout the year. In addition, the production of maize fodder and feed for livestock has fueled the adoption of maize agriculture throughout the developing countries of Asia and Africa. Maize provides the world's most cost-effective and highest yield plant resource currently available for the production of livestock forage, fodder, and feed (Dowswell et al., 1996, pp. 27–28).

**Old World dispersals.** The cultural, economic, and political impacts of the European discovery of maize were evident in the ensuing population boom that followed its introduction into the Old World. After 1492, maize rapidly diffused into Europe, Africa, and Asia and was successful in large part because it did not directly compete with existing grain crops such as rice, wheat, oats, millet, and barley. Maize was also suited to cultivation in otherwise poor growing conditions related to topography, soils, climates, aridity, and elevation. Significantly, maize also prospers in exceptionally wet climates unsuited to wheat or relatively arid regions unsuited to rice cultivation. Moreover, maize has the additional advantage of rapid returns and twice the productive yield per unit of land of wheat.

The adoption of maize in Africa and China heralded a dramatic social and cultural transformation. Maize provided a level of food surplus that permitted the exponential growth of populations. Whereas in Europe maize was seen as a substandard cereal grain, fit only for feeding the poor and hungry and livestock, in many areas of Africa and Asia maize came to dominate the agricultural economies of many nation-states. The productivity and efficiency of maize horticulture and its low production and transportation costs made it a cheap food for slaves captured and held by European and Arabic slave traders. Maize made possible the efficient and economical transport and exchange of horrific numbers of sub-Saharan Africans destined for the markets of Europe, the Middle East, and the Americas.

### The African Connection

Although it remains unclear who first introduced maize to Europe, Africa, and the Old World more generally, a number of scholars now argue that the Portuguese colonies of Africa served as the initial conduit to the dif-

fusion of maize in that hemisphere. Jean Andrews claims that maize, beans, peppers, squash, and turkeys diffused into the Balkans, or southeastern Europe, by way of Portuguese Africa, India, and the Ottoman Empire in the period following the voyages of Columbus (1993, pp. 194–204). So profound was the impact of maize on the African economy that, like Mesoamerica, culture and society, subsistence and settlement, political economy and gender relations, and the respective cuisines and culinary technologies of each of these vast regions were rapidly transformed to accommodate the adoption of maize and those human diasporas with which it was associated. The unique maize-based cultural complex of agricultural practices, extensive settlement patterns, and storage, distribution, and food processing technologies identified with maize cultivation in fact fueled much of the transformation in question. In *Africa's Emerging Maize Revolution*, Derek Byerlee and Carl Eicher acknowledge that the adoption of maize has been the primary engine driving the transformation of the African social, political, and economic landscape for the many societies that have been swept up in this new agricultural revolution.

More specifically, it is becoming increasingly evident that those agricultural practices identified with maize, such as swidden cultivation, extensive or shifting settlement patterns that are, in turn, identified with swidden systems, the processing of maize with basalt grinding slabs, the female domination of these labor-intensive food processing and storage traditions, and the emerging role of women in the maize-dominated marketplace have all played significant roles in the transformation of the African political economy. Moreover, given the fact that in many areas of Africa, much of the traditional African agricultural complex—centered on such crops as millet—has been displaced by maize has much to do with the changing face of African cuisine at the most fundamental level of analysis, and more generally, at the interface of cultural change and transformation.

Africans prepare a maize porridge—called *kpekple* in Ghana, *bidia* in Zaire, *sadza* in Zimbabwe, *putu* in Zululand, *mealie* in South Africa, and *posho* or *ugali* in East Africa—consumed by millions. Virtually no African country has remained untouched by the diffusion and exchange of maize, and the agricultural practices on the African continent range from the simple sowing of maize kernels along rivers and streams to the cultivation of maize in household gardens. While widespread, these traditional practices are primitive compared to the magnitude and intensity of agribusiness development and investment in commercially viable maize agricultural field systems.

### Maize Procurement and Processing

Maize is seldom described outside of the so-called Mesoamerican triumvirate of maize, beans, and squash. Early Mesoamerican peoples planted these food crops together, often planting beans and squash adjacent to maize so as to provide the former plants stalks on which to ex-

## MAIZE-TORTILLA TECHNOLOGIES

Neolithic maize-tortilla technology persisted well into the late nineteenth and early twentieth centuries throughout Mesoamerica, and the Americas more generally. It did so in large part due to the unique lime processing of the soaked and softened maize kernels for *nixtamal* used in Mesoamerica. This maize dough by-product was then washed so as to remove the pericarp, or outer skin of the individual kernels, and was ground on metate grinding platforms. Apparently, the resulting mix of moist flour (*masa*) was then processed into tortillas.

The use of metate grinding slabs and the pestle (*metlapilli* or *tejolote*) provided a range of nutritive and socioeconomic benefits: (1) reduction, fractionation, and mineral supplementation of maize kernels, (2) lime treatment, (3) the shearing stroke used to process maize kernels, (4) craft specialization and the appearance of markets oriented to the production and exchange of maize-tortilla technologies, (5) nutritional and subsistence economics of maize preparation, (6) the social and economic reorganization of maize preparation, including cooperative production among households and the appearance of specialists such as tortilla vendors, and (7) the emergence of maize-tortilla technology and equipment—including *comalli* or *comal* ceramic griddles—that were indicators of social or economic status.

As for the persistence of maize-tortilla technologies specific to the metate and *tejolote*, because tortillas require a very finely ground *masa*, the adoption of power milling (*molinos de nixtamal*) of maize flour for the production of tortillas was not generally adopted until the improvement of power milling technologies in the 1940s and 1950s. Male heads of household resisted the adoption of power milling technologies because the thirty-five to forty hours per week required to hand mill *masa* on the traditional metate grinding slab was construed as women's work. Women, however, generally favored the adoption of the new *molinos de nixtamal*, and between the years of 1935 and 1940 the number of *molinos* (power mills) in Mexico increased from 927 to almost 6,000. The efficiency of the power mills freed women for other household tasks, including those pertaining to their newfound roles, industries traditionally reserved for males, in the marketplace and arts and crafts. Similar patterns affecting the displacement of men and or the relegation of women to maize-processing industries have been identified with the adoption of maize agriculture in Africa, Europe, and other regions of the Old World. In fact, the metate identified with Mesoamerica is now a familiar feature of that material culture associated with both women's daily activities and the African kitchen more generally.

tend their vines. Mesoamerican cuisine similarly combined the products of these plants in a culinary mix that reinforced and supplemented the otherwise niacin-poor composition of maize-dominant dietary practices. Without these supplements, or the lime processing inherent in the production of *masa* (maize flour) used in the production of tortillas and related foodstuffs, maize-dominant diets have the potential to result in the spread of the skin disease pellagra. Pellagra spread rapidly and in epidemic proportions throughout all the European and African countries that first adopted maize consumption without similarly adopting the critically important *nixtamalización* process necessary for the production of *nixtamal* or lime-treated *masa*. The source of the disease remained a medical mystery until it was studied in the context of maize consumption in the southern United States. It was ultimately determined that the niacin-deficient nature of maize-dominant diets played a key nutritional role in the onset of those symptoms identified with pellagra.

### Traditional Maize Agricultural Systems

In Latin America, maize is the central foodstuff of the hearth and household. Because of the broad range of cli-

mates, soils, and topographic and hydrological conditions under which maize may be cultivated, diverse agricultural methods have evolved to accommodate its cultivation and processing. Maize environments in the Third World have been classified into four major types: tropical, subtropical, temperate, and highlands. As of 1996, tropical environments accounted for 90.6 million acres, or 45 percent of the total area under maize cultivation in developing countries; temperate environments accounted for 55.1 million acres, or 27 percent of the total; subtropical environments accounted for 42 million acres, or 21 percent of the total; and highland environments constituted 15.3 million acres, or 8 percent of the total area under maize cultivation in the developing world (Dowswell, Paliwal, and Cantrell, pp. 38–46).

In the tropical forests of Mexico and Central America, maize agriculture is predominantly associated with swidden (slash-and-burn or shifting) agricultural systems and the development of *milpas* (maize fields). Swidden cultivation entails the scoring or felling of trees and the subsequent torching of dry foliage and timber left in the wake of the clearance operation. Once the forest parcel has been cleared, dibble sticks are used to pierce the soil

### CUITLACOCHÉ: AKA “CORN SMUT”

Of the many ancient and traditional food by-products of maize, “corn smut” (*Ustilago maydis*), a fungus called *huitlacoche* or *cuitlacoche* by the Mexican Aztecs, continues to hold its own as one of the more popular delicacies of Mexican cuisine on the U.S. market. *Huitlacoche*, comparable to the Portobello mushroom in some respects, is a soil-borne fungal growth that affects the internodes, the base and midrib of leaves, and immature ears of maize. This fungus is but one more in a constellation of foodstuffs not previously considered for the modern marketplace. In fact, it has been surmised that corn smut may soon become a part of the nouvelle cuisine in the United States. Like the skepticism that greeted the initial introduction of maize in Europe, it may take time before corn smut becomes popular with consumers.

Corn smut accounts for some 3 to 5 percent of maize crop losses or damage in the United States alone. As such, it will likely provide a continuing source of economic incentives to U.S. farmers prepared to define a market niche for the maize-based fungal growth.

for the sowing of maize kernels in the charred timbers of the *milpa*. In contrast, in highland Guatemala maize is cultivated on the steepest of mountain slopes and under the most challenging topographical and hydrological conditions. In highland central Mexico, on the other hand, maize cultivation took the form of *chinampas* (floating gardens)—perhaps the most unique agricultural system devoted to maize—that rapidly evolved and proliferated in the Basin of Mexico in pre-Columbian times. In fact, *chinampas* were a fundamentally important aspect of agricultural development in the highly populated Basin in the precontact period from the thirteenth to sixteenth centuries C.E. Earlier forms of agricultural intensification associated with both *chinampas* and maize cultivation have similarly been identified with the ancient metropolis of Teotihuacan, Mexico. This ancient city, which contained a population of some 150,000 people within an area of just under 8.5 square miles, was sustained through such productive systems of agricultural intensification during the period from 100 to 650 C.E. The only remaining Mesoamerican examples of this form of agricultural intensification are found in Xochimilco, Mexico.

In essence, *chinampas* entailed the creation of new agricultural parcels of land built atop floating islands or enclosures created within the shallow margins of Lake

Texcoco. *Chinampas* plantations were framed within long, narrow rectangular enclosures formed from willow branches staked into the depths of the shallow lake bed—that part of a system of lakes identified with Lake Texcoco—that once dominated the Basin of Mexico. Earth and mud gathered from the shallow lake bottom were dumped into these enclosures and used to form the agriculturally viable portion of those *chinampas* that were eventually anchored to the shallow lake bottom through the growth of those willow shoots and branches used to stake the plots. The recurring introduction of nutrients for maize grown atop *chinampa* parcels entailed the use of lake bottom mud, silt, vegetation, and excrement in an otherwise effective and ecologically sound practice. In this way, the Mexican Aztecs and their predecessors increased their ability to feed a rapidly growing Basin population by expanding the amount of cultivable lands devoted to maize and related crop systems. The area identified with the lakeside community of Xochimilco in the southern Basin of Mexico continues the practice of *chinampa* cultivation and floating gardens, and such parcels enable Mexican farmers to excel at the production of maize, beans, squash, flowers, and a variety of other Mesoamerican crops.

In the Maya lowlands and along the coastal margins of the Yucatan peninsula, the ancient Maya devoted considerable resources to the production of maize and related crops in raised or ridged field systems. These massive ridged field systems are among the largest and most extensive earthworks ever produced by the Maya or other societies of ancient America. Created within swamps, flooded *bajos*, or water-filled shallow limestone sinks or coastal estuaries, raised fields (or ridged islands or embankments) were formed into elongated, roughly rectangular agricultural parcels by piling soils or upcast scooped from drained areas immediately adjacent to the embankment or island. The overall appearance of such fields resembles massive waffle-like garden grids. These individual islands, however, were broad enough to accommodate the passage of a tractor-trailer rig. Pollen studies from these large earthen constructions have determined that, while maize was the major product of these systems, a variety of other Mesoamerican foodstuffs were also cultivated. In fact, the quantity of foods produced by such systems far exceeded the amount projected for swidden agricultural systems (once thought to be the predominant means by which food was grown in the tropical landscapes of the Maya heartland).

Whether produced by the indigenous systems of *milpa* or *chinampa* agriculture, maize cultivation in much of the Third World, and in more traditional contexts, has been dominated by the use of the “dibble stick” since pre-Columbian times. Consisting of a shaft of wood with a pointed tip used to pierce the soil for the sowing of maize kernels, the dibble stick has persisted for thousands of years and has been adopted by subsistence farmers throughout developing countries that have adopted maize agriculture. Nineteenth-century American maize farmers

adopted both the cylindrical silo or “corn crib” and the “dibble stick” from American Indian prototypes (Fussell, p. 152). Improvements on the dibble stick developed in the 1850s ranged from the Randall and Jones Double Hand Planter to the long-lived “Stabber” or “Jobber.” Both of these variations “stab” the soil and simultaneously dispense maize kernels into the holes (Fussell, pp. 144–146). Such early efforts ultimately led to the evolution of the automated maize planters of today. Unlike commercial systems of mass production identified with the technology of maize planting and cultivation, the dibble stick has weathered the introduction of new techniques and continues to dominate more traditional, nontechnological farming practices around the world.

### The Maize Harvest of the Machine Age

One need only travel to places like the state of Nebraska to realize that maize agriculture dominates the agricultural traditions of some societies. In fact, a drive through Nebraska during the growing season might leave some outsiders with the impression that it consists of a seamless, seemingly endless, and very dense field of maize. For the past two hundred years, farmers and agricultural scientists in such areas have developed a variety of means, technologies, and hybrids suitable for the continuing propagation of maize. In *The Story of Corn* (1992), Fussell summarizes the many agricultural technologies, cropping and harvesting methods, hybrids, commercial products, and cultural and religious values identified with maize agriculture in the Americas and other parts of the world.

Methods of harvesting of maize range from the hand culling of hybrid maize cobs from home gardens to towering high-tech combines or harvesting machines and tractors rigged—in the largest combines—to cull maize ears or cobs at the rate of twelve rows at a time and thousands of bushels per day. Even an older combine or harvester can harvest some 10,000 bushels of maize per day, yielding 150 to 200 bushels per acre. On the other hand, the maintenance and upkeep of such machines easily runs into the thousands of dollars per year, an amount likely to double or triple in the Third World. A new combine harvester can cost from \$100,000 to \$200,000 or more in the United States. Whereas subsistence farmers throughout much of the Third World continue to thresh maize by hand without specialized equipment or resources, this task is left to agribusiness giants and commercial agricultural concerns in industrialized nations.

An array of farm machinery patents for the harvesting and processing of maize appeared shortly after the industrialization of farms. The U.S. Patent Office Report of 1860 lists hundreds of patents for corn planters, cultivators, harvesters, cornhuskers, corn shellers, cornstalk cutters, corn-shock binders, cornstalk shocking machines, corn cleaners, seed drills, rotary harrows, smut machines, corn and cob crushers and mills, and seed drills (Fussell, p. 144). The advent of the canning industry in 1862 and the proliferation of new land-grant colleges de-

voted to science, agriculture, and industry helped fuel the industrialization and modernization of maize procurement, processing, storage, distribution, and hybridization. In time, the industrialized farming operations and agricultural cooperatives of the Corn Belt adopted many mechanized methods for harvesting and threshing maize. Soon thereafter the towering grain silos and high-rise grain elevators of the Midwest replaced the humble corncribs adopted from the North American Indians. Despite this, traditional household corncribs survived the onslaught of the Industrial Age, and survivals include the Mesoamerican *cuezcomatl* (thatch-roofed adobe brick granary), the crib-logged granaries of the Sierra Tarahumara Indians of northern Mexico, and the clay-lined maize grain silos of Africa. In each instance, subsistence farmers and agribusiness giants alike must take into account the difficulties of storing maize at optimal conditions and balance humidity, the moisture content of the kernels, and the potential for pest infestations.

### The Future of Maize

Maize is processed into a dizzying array of consumer products ranging from corn on the cob and popcorn to cornstarch, corn oils, automotive fuels, such as ethanol and gasohol, and alcoholic beverages, including corn beer (*chichi*) and whiskey. In addition to the more than 1,000 maize-based products that one is likely to find in the local supermarket, the genetically modified by-products of maize are creating their own culinary diversity and potentials, pitfalls, controversies, and complications for the world of food production and biotech industries. Beyond the diversity inherent in the production and distribution of maize in the marketplace, the reality is that maize remains the most important agricultural crop for over 70 million farm families worldwide. Eighty percent of the world's farmers who cultivate maize are in developing nations of the Third World. This reality, coupled with the “genetic erosion” of the crop, has prompted some to ask

whether maize can be bred so as to assure the sustainable evolution of the crop (Sevilla, p. 221). If the lawsuits for patent infringements against farmers by agribusiness corporations and biotechnology firms for the unlicensed use of their patented hybrids are any indication, the potentials of genetic diversity and hybrid vigor once identified with maize may be constrained to ever fewer and increasingly more vulnerable hybrid offspring.

#### MAIZE AS A FOOD

The evolution, dispersal, and consumption of maize span the better part of the past eight thousand years of human cultural development. Until European exploration in the Americas began in 1492, maize was a New World domesticate with an exclusively American distribution and consumption. After 1492, maize rapidly diffused throughout the Old World of Europe by way of ships returning from the New World. In fact, by 1498 cultivation of maize had begun in Seville, Spain. With its subsequent adoption in Africa for the purpose of feeding the growing numbers of African slaves destined for southwest Asia and the Americas, consumers throughout Africa, Europe, and Asia began to use maize as food and

as fodder. According to Sophie D. Coe's review of America's first cuisines, maize constitutes the third most important food crop in the world, following on the heels of wheat and rice (p. 10). It is no accident, therefore, that maize constitutes a fundamental ingredient in many of the world's cuisines, ranging from Mexican enchiladas and Chinese baby-corn, to African-American grits, corn flakes, popcorn, Italian polenta or gruel, corn meal, maize-based alcoholic beverages (such as whiskey and bourbon), mayonnaise, and corn oil. Thus, maize has more than demonstrated its cross-cultural adaptability, gastronomic significance, and culinary versatility.

### Maize Preparation and Consumption

The preparation of maize into food and beverages subsumes a world of food and beverage variations. Maize-based foods and beverages in Mesoamerica—the place where maize originated—are many and diverse, and many of these are quite old. In Mexico alone, food and beverage varieties range from those by-products of maize that derive from the food process known as *nixtamalización* (or nixtamalization) to the fermentation of processed maize into alcoholic beverages and the creation of a very broad variety of foods. The oldest and most enduring method for processing cereal grains is one that originated in ancient Mesoamerica long before the Common Era.

### Nixtamal Production

In order to produce any one or more of the aforementioned maize-based foods or beverages, maize must be reduced to a paste or flour. The resulting by-product was known to the Mexica-Aztecs as *nixtamal*, and the process for rendering the maize kernels into a paste has since come to be known as *nixtamalización*. According to Sebastián Verdi, *nixtamalización* entails the fundamental process of rendering maize kernels into a paste that is treated with lime and heat in order to incorporate calcium and digestible iron into the *masa*, or maize dough. Ultimately, *nixtamalización* enhances the nutrient content of tortillas and related maize food by-products in such a way that maize is rendered superior in nutrient value to other grain-based foods such as white bread (p. 9).

In their study of the physiochemical, structural, and textural properties of tortillas and the *nixtamal* process, G. Arámbula-Villa and colleagues provide a detailed overview of the distinctions inherent in the methods and mechanics of the *nixtamalización* process. In comparing the efficacy and mechanics of traditional methods of dry-*masa* flour production versus modern methods of instant-*masa* flour production, these researchers present two detailed diagrams (p. 246). The traditional dry-*masa* production method entails several distinct steps, including cooking, steeping, *nixtamalización*, washing, *nixtamal*, milling with a hammer mill, drying, re-milling with the hammer mill, classification, and product collection. The modern production of instant *masa* entails dry milling, the mixing of water and lime with ground maize, extru-

### TARAHUMARA INDIAN *TESGÜINO* PRODUCTION

Anthropologist Bernard Fontana has documented the process identified with the production and fermentation of the maize beverage known as *tesgüino* to the Tarahumara Indians of Chihuahua, Mexico. This fermented maize drink may be processed from newly sprouted maize or malt, even though other variants of *tesgüino* may be processed from roasting maize ears or the fruit of the nopal cactus, shrubs, and selected fruit trees. The Tarahumara recipe for *tesgüino* is as follows: Maize kernels are distributed along the bottom of shallow baskets. The baskets are then covered with grasses and placed in a darkened location where they are sprinkled with water daily for four or five days, so as to stimulate the sprouting of the maize kernels contained therein. When the maize sprouts are approximately one inch in height, they are ground on a ground stone slab or metate and placed into pottery jars or metal bowls containing water. These are set to boil for approximately eight hours. Once the liquid acquires a yellowish hue, it is left to cool. The liquid is then strained into another bowl and mixed with other herbs to produce a paste into which more water is added. The mixture is then placed into specialized fermenting vessels that are stored in a warm location for the evening. The watery paste is then mixed with the strained maize broth and allowed to ferment for three to four days. Ultimately, *tesgüino* is intended for festive occasions such as the *rarájipari* kick-ball game and related rituals, and it should be consumed immediately since it begins to spoil within twelve hours of completing the recipe (p. 54).

sion or *nixtamalización*, fresh *masa*, drying, milling with a hammer mill, and product collection.

*Nixtamalización* often involves the use of a lime or alkaline bath or pre-soak that results in the softening and “shelling” of maize kernels. Once softened, the maize kernels are rendered or ground by way of basalt-stone grinding technologies, such as the ancient metate grinding slab or the modern automated *molinos*, or maize grinding mills, that pulverize maize for preparation into such by-products as *masa* or maize dough. *Masa* is used predominantly in the production of the pancake-like maize cakes or flat breads known as tortillas. *Masa* is also used in the production of a broad variety of foods and beverages, including the ever-popular corn-husk encased Mexican *tamale*, *totopos*, or *tostaditas*. *Masa* is also used in the Mexica-Aztec ground maize drink or gruel known as *atolli*

A frontier settler in Potter County, Pennsylvania, is shown using a hominy block for crushing corn to make grits. The pestle is attached to a sapling, which allows for easier pounding. Woodcut, circa 1840. ROUGHWOOD COLLECTION.

or *atole*, in *champurrado*, which consists of a rich broth of *atole* mixed with chocolate, and in the alcoholic beverage known to the Tarahumara Indians of northern Mexico as *tesguino*. Many of these indigenous Mexican foods and beverages have been adopted or reinterpreted by agribusiness, nutritional scientists, the general public, and the food industry. Such foods are distributed internationally under such brand and trade names as Quaker *masa harina* (dough flour), Fritos, Taco Bell, Corn Chex, Kellogg's Corn Flakes, Doritos, and many others.

### Maize Nutritional Composition

Scientists from several disciplines have studied the tortilla and its counterpart the tamale as examples of the nutritional value or mineral composition of processed maize products. In one such study conducted in 1988 and 1989, nutritional scientist Charles Weber and colleagues studied commercially produced tortillas and tamales from food chain stores. The tamales in this study included both green corn and stuffed beef and pork varieties. The researchers contrasted those tortillas and tamales with others produced in neighborhood factories or outlets and homes in the Mexican-American barrio communities of Tucson, Arizona. Thus, the results of these studies provided one basis for understanding the nutritive values of processed maize as represented by both commercial and domestic by-products. The study demonstrated that there was little variation in the size, composition, and mineral content in the commercially milled tortillas obtained from different commercial outlets.

The findings also demonstrated that the average size and weight of the maize or corn tortilla were 5.7 inches and 0.71 ounces, respectively. Average moisture content

was 42.9 percent; protein content was 5.9 percent; lipid values were 2.3 percent; and acid detergent fiber and ash values were 1.8 percent and 1.3 percent, respectively. Carbohydrate content averaged 49 percent, while energy values averaged 240 kcal/100 grams (pp. 326–327). In contrast, tamales averaged 4 ounces in weight; moisture content averaged 59 percent; protein values averaged 5.4 percent; and lipid concentrations varied considerably but averaged 11 percent. This latter variation was thought to be the result of the wide variety of recipes used to produce tamales, and the variable use of fat sources such as lard versus hydrogenated vegetable oil. Also, it should be noted that whereas beef tamales averaged 4.2 ounces in weight, green corn tamales averaged 3.5 ounces in weight (pp. 330–331). Finally, in regard to mineral content, Charles Weber and his colleagues found that maize or corn tortillas contain calcium, phosphorous, iron, zinc, copper, and magnesium in variable amounts. Their study also noted that the calcium content of tortillas produced from lime-processed *nixtamal* was ten to twenty times higher than that of the original grain source (pp. 331–332). These studies demonstrate that the dry milling and lime processing of maize at the most fundamental level have a profound effect on the inherent nutritive values of maize.

### Pellagra and the Indian Triad

Because of the inherent nutritional values and mineral composition of maize grain, the lime processing of *nixtamal* and the evolution of the so-called “Indian triad” or “Mesoamerican triumvirate” were critical innovations that were directly attributable to the ancient Native Americans who nurtured maize through much of its evo-

## FROM AREPAS TO BLUE CORN PIKI

*Arepas* are to Venezuelans, Colombians, and Peruvians what tortillas are to the Mexican people. In order to prepare *arepas*, dry white maize kernels are ground into flour, which is then mixed with water, oil, and salt, and then prepared in much the same way that tortillas are formed, except in this instance, the flat breads are smaller but much thicker in shape than tortillas. The larger and thicker tortillas, which characterize the maize flat breads of the Nicaraguans, allow for larger servings of beef or other ingredients to be placed in the tortilla-like container. The *pupusas* of El Salvador, prepared from lime-treated maize with the addition of cheese, are essentially smaller tortillas that are used primarily for burritos or taco-like containers of beef or chicken and legumes and vegetables. The *humitas* of Bolivia and Chile are yet another form of tamale consumed in South America. Invariably, pre-cooked maize flour similar to lime-treated *masa* is mixed with other regional ingredients to produce *humitas*.

The Hopi Indians of Northern Arizona have processed maize into a particularly unique food known as *piki* bread for the past eleven centuries. *Piki* bread consists of a very thin, gray, and ashy maize tortilla or wafer created from blue corn meal by way of hand-coating a very hot and finely polished stone griddle with a watery maize dough paste. In *The Story of Corn*, Betty Fussell cites Hopi matriarch Helen Sekaquaptewa's acknowledgement that "*Piki* are the original cornflakes," thereby noting that these otherwise paper-thin, flaky, and quite tasty *piki* blue-corn wafers inspired the subsequent development of flaked corn (pp. 167–168).

lutionary history. The triad or triumvirate in this instance refers to the American Indian horticultural heritage and/or tendency to cultivate maize, beans, and squash together in the same agricultural plots and, subsequently, to mix these ingredients into their culinary repertoire in a nutritionally balanced and sophisticated way. The combination of maize with both beans and squash is culturally and biologically critical in that the nutritional value of maize is significantly enhanced by the addition of these two fundamental foods. While maize lacks the amino acid niacin, common beans (*Phaseolus vulgaris*) are a significant source of amino acids, including niacin, tryptophan, and lysine. In her account of the *nixtamalización* or lime processing of maize developed in ancient Native America, Betty Fussell documents the means by which this process transforms maize's inherent protein structures (mainly albumins, globulins, glutelin, and zein) into the metabolically and nutritionally critical amino acids niacin, tryptophan, and lysine (pp. 203–204).

The maize-dominant diets of some European, Egyptian, and other African peoples at the end of the nineteenth century lacked the aforementioned essential amino acids. This lack resulted in the spread of pellagra in epidemic proportions. Kwashiorkor—a severe form of malnutrition identified with infants and children dependent on high-carbohydrate and low-protein diets—also appeared among African and other peoples whose diets were maize-dominant. In her book on the culture and agriculture of tomatoes, potatoes, corn, and beans, Sylvia Johnson notes that those afflicted with pellagra suffered skin rashes, dizziness, sore muscles, and in the worse-case scenario, insanity and death (pp. 24–25). According to Betty Fussell, to Europeans pellagra was widely known as “corn sickness” until it was renamed pellagra by an Italian in 1771 (p. 202). Even so, the specific causes of pellagra remained a mystery until after 1915, when the U.S. National Institute of Health commissioned a pellagra investigation headed by Dr. Joseph Goldberger, whose findings ultimately led to the effective treatment of the disease in the United States by the 1930s. These deficiencies and the epidemics with which they were associated might have been averted with the adoption of the “Indian triad” and the alkaline or lime processing of maize into *nixtamal*. According to Betty Fussell, this variety of maize processing can be documented to as early as 100 B.C.E. through the discovery of lime-soaking pots at the ancient site of Teotihuacan. She concludes that such discoveries have led many to believe that “corn is the oldest chemically processed grain in the world” (p. 176).

### The Primordial Maize Tortilla

The maize flat breads or tortillas of Mexico are ancient and ubiquitous in the Americas. These breads are a fundamental staple of Mexican and other Latin American cuisine and have inspired the creation of a wealth of pre-Columbian or indigenous American foods, including en-

chiladas, tacos, tostadas, *sopes*, *flautas*, *chilaquiles*, and *sopa de tortilla*. The principal distinctions in these foods evolve from the treatment of the tortilla. In these Mexican food examples, tortillas are rolled, folded, flattened, thickened, and or fried. In the case of *chilaquiles* and *sopa de tortilla*, old, hardened, or otherwise stale tortillas are broken up or cut into strips and used in the preparation of casseroles and soups. In most of the aforementioned examples, the tortilla serves as the container, packet, or flat bread into or upon which varying types and quantities of meats and vegetables are placed. Alternately, the tortilla becomes but one additional, albeit important, ingredient in the preparation of casseroles and soups. Sophie D. Coe acknowledges that late-fifteenth and early-sixteenth-century Mexica-Aztec peoples of the Valley of Mexico

Men of the Kamba tribe in Kenya drink maize beer from gourds. It was common in earlier times for the men to drink the beer with straws from a common gourd. PHOTO BY Y. MORIMOTO.

used tortillas and steamed maize-dough tamales as containers or packets for an incredible variety of foodstuffs, including beans, squash, tomatoes, mushrooms, avocados, worms, rabbit, deer, turkey, and many other items (pp. 112–119). Heriberto García Rivas has also investigated the extraordinary wealth and variety inherent in the maize-based pre-Columbian cuisines of Mexico.

In addition to its status as the premier Mexican foodstuff, the tortilla is also part of indigenous and Catholic religious traditions and rituals in Mesoamerica and beyond. Aside from their status as the gastronomic and culinary archetype of maize-based foods, tortillas also serve a practical need in their role as edible utensils (spoons or spatulas) used for scooping up beans, rice, and meats served in Mexican cuisine. In fact, legend has it that Motecuhzoma Ilhuicamina—the illustrious penultimate emperor of the Mexica Aztec—never used the same eating utensils more than once. This was due in large part to the fact that the emperor used tortillas in the same way that the Spanish used spoons and other utensils in the Old World. In many areas outside of Mexico (including the southwestern United States) tortillas have taken on a culinary predominance: they are regularly substituted for breads and other carbohydrates. This phenomenon was unheard of in colonial times. For example, in New Spain or Spanish colonial Mexico (c. 1521–1821), those who believed maize to be an inferior food fit only for the feeding of swine often substituted wheat for maize in the pro-

duction of tortillas. From that point forward, wheat or flour tortillas took on a status as the flat bread food of choice for Spanish colonials in Mexico, whereas tortillas prepared from maize continued to be perceived as the primary foodstuff of Mexican Indians and the poor. Ironically, what were once called *totopos* or *tostaditas* in Mexico are today called “corn chips,” such as Doritos, Fritos, and nachos, which are a widely consumed snack food in the United States and elsewhere.

### Other Traditional Maize Foods

Once maize was introduced into the Old World of Europe, foods containing maize as a main ingredient were created for a variety of distinctive dishes and regional palettes across that vast cultural region. Italians adopted maize into a dish today known as polenta, which consists of a finely ground maize mixed with water in order to produce a porridge or mush. Sylvia Johnson describes polenta as a maize mush cooked in a pot, poured onto a wooden board, and allowed to cool for a few minutes until ready to consume. Eventually, polenta was mixed with other ingredients typical of Italian cuisine including grated cheese, mushrooms, tomatoes, and peppers, or it was served with pasta. When mixed with sugar or honey, polenta took on one other food use: as breakfast porridge (p. 21). In Rumania, *mamaliga* is prepared from sweet cornmeal and consists of a food akin to polenta that is sometimes referred to as “cornmeal mush.” Cornmeal re-

mains a primary staple of Rumanians and Hungarians alike, with *puliszka* being the staple food of Hungarians. *Puliszka* is prepared in much the same way as either polenta or *mamaliga*; however, it is often topped with feta cheese, butter, and other ingredients lightly blended into the cornmeal mush before the meal has been thoroughly cooked. Also popular in Romania and Hungary is *malderash*, which consists of maize cakes seasoned with cumin and coriander.

### African Maize Cuisine

In the sixteenth century, maize rapidly diffused across the African continent as a result of the slave trade. By the end of the nineteenth century, a maize meal called *posho* was among the most popular foods of eastern Africa. Sylvia Johnson notes that the primary African use of maize as a food is in mush or porridge. Africans grind and boil maize in water in much the same way Europeans and Americans have done for many years (pp. 236–237). Maize porridge is known as *kpekle* in Ghana and *bidia* in Zaire. In Zimbabwe, people consume *sadza*, whereas East Africans eat *posho* or *ugali*. Zulu-speaking people consume *putu* as a primary source of nutrition. One African dish called *coo-coo* contains maize mush with okra, an African vegetable that slaves introduced in the Caribbean as fungi (pp. 22–23). In Nigeria, maize is boiled and roasted in different forms. For example, *adalu* consists of maize kernels or cornmeal boiled with beans, while *ogi* and *tuwo* consist of ground and boiled maize flour. *Ogi* is a breakfast dish prepared from maize flour that is boiled until it attains a smooth consistency. *Tuwo* also consists of maize flour that is boiled until it acquires a thick consistency. Nigerians generally consume *tuwo* with soup dishes. Similarly, *kokoro* is a Nigerian snack food comprised of ground maize dough rolled together with other ingredients and then fried in vegetable oil. Finally, *aadun* consists of a cooked or baked snack prepared from ground maize, red pepper, and oil. Invariably, many of those maize foods developed in Africa found their way back to the New World by way of the Caribbean and have lasted in the African-American culinary tradition. Grits can also be added to this list of African maize culinary concoctions. Grits consists of coarsely ground dried corn and is used as an ingredient in any number of other maize-based recipes, ranging from cracklin' cornbread to corn chowder, fried catfish basted with yellow corn meal, and a host of cornbread stuffings and hominy-based recipes.

### Maize as a Fermented Beverage

According to a Food and Agriculture Organization report, the fermentation of maize by indigenous Latin American peoples provides the basis for virtually all indigenously produced alcoholic beverages in the Americas. *Chicha de jora*, or maize beer, is perhaps the most important and popular beverage produced in South America, including the countries of Argentina, Bolivia, Brazil, Colombia, Ecuador, and Peru. In fact, according to Betty Fussell, *chicha* was the critically important nu-

### MAIZE: MYTH AND SYMBOL

The *Popol Vuh*, the sacred book of the ancient Quiche Maya, relates an origin myth that illustrates the role of maize as the hearth and source of Mayan culture and civilization itself. According to the Maya, the ancestors were fashioned from maize and bitter water. Thus depictions of maize plants and foods in the form of human-maize anthropomorphs in Mesoamerican ceremonial and ritual contexts are common. The seventh-century polychrome murals of Cacaxtla, Mexico, present depictions of maize stalks with cobs in the form of human heads bearing Maya-like features and hair consisting of maize silks. Dennis Tedlock's translation of the *Popol Vuh* notes that in order to create the first human ancestors, it was necessary for the female deity and midwife Xmucane—"the Bearer, Begetter, Sovereign Plumed Serpent"—to grind the yellow and white maize nine times in order to render whole the flesh of the earliest ancestors (pp. 145–146). Through this most ancient of legends and cultural lenses, the Maya continue to interpret their world, and in turn, be interpreted by the world about them. According to anthropologist Evon Z. Vogt, the Zinacanteco Indian healers and shaman of Chiapas, Mexico, conduct ancient and traditional rituals that make use of maize kernels, which are still viewed as a model for the structure of the human soul (pp. 94–95). In addition to the spiritual and divinatory place of maize in both ancient and modern Maya cosmology and worldview, Zinacanteco and other Mayan healers prescribe maize in a variety of forms as a remedy for any and all spiritual and physical conflicts.

According to the Food and Agriculture Organization, the Lacandon Maya used *pozol* with water and honey to reduce fevers. At the same time, *pozol* was used as cataplasm to heal minor wounds and to counter the effects of diarrhea. According to Jorge Fernandez Chiti, a tea was blended from *barbas de elote* (corn silk or maize tassels) and this concoction remains a popular Latin American diuretic used in natural healing and medicine in this day and age. *Barbas de elote* continues to be used by Latin American *curanderos* or "curers" for the treatment of kidney and bladder problems, as well as a remedy for hepatitis and edema (p. 59).

tritional counterpart to the *nixtamalización* and ash-and lime-processed maize products used in other areas of the Americas (but unknown in Andean South America) in pre-Columbian times (p. 249). Other alcoholic beverages

## ATOLE: AN AZTEC BREW

According to Heriberto García Rivas, *atole*, from the Aztec term *atolli*, signifies watery or watered-down liquid or beverage. *Atole* is one of the preferred maize-based drinks of the indigenous peoples of Mesoamerica. Since remote antiquity, *atole* has been prepared from boiled fresh maize ground into *nixtamal*. Once rendered into *nixtamal*, this by-product is boiled with a variety of ingredients including sugar, milk, and water to produce *atole*. In Mexico, when *atole* is mixed with chocolate it is called *champurrado*. The sixteenth-century Franciscan chronicler Bernardino de Sahagún documented information from his Mexican Aztec informants regarding the different kinds of atoles available in New Spain since pre-Columbian times. Heriberto García Rivas adds that beverages identified by Aztec-era chronicler Sahagún included *totonquiatulli* or hot *atole*, *necuatolli* or *atole* with syrup or honey, *chinecuahmolli* or *atole* with syrup and yellow chili, *guanexamolli* or *atole* processed from a thick or pasty *nixtamal* mix (p. 46). *Atole* is available from street-based food vendors and Mexican restaurants that serve traditional specialty food items in Mexico, Central America, and in many areas of the southwestern United States.

fermented from maize dough or flour include *abati*, consumed primarily in Paraguay and Argentina; and *chica*, *charagua*, *ostoche*, *sendechó*, *zambumbia*, and *tesgüino*, all consumed in Mexico. *Sora*, or maize beer, is also consumed primarily in Peru. For Latin America, maize-based non-alcoholic beverages and porridges include *acupe* from Venezuela; *cachiri* and *fubá* from Brazil; *champuz* and *napú* from Colombia and Peru; and *pozol*, *sendechó*, and *atole* from Mexico. When producing *pozol*, a mixture of water and lime is mixed in a suitable container and maize is added to the aforementioned mixture and boiled. Once *nixtamal* has been prepared, the by-product is washed and ground into maize dough, which is then shaped into small balls and covered with banana leaves. The fermentation of *nixtamal* is necessary for the production of *pozol*, which ultimately requires one to fourteen days to produce.

Whereas maize is a primary staple of American Indian maize-beer production, in North America its use is best known from the Prohibition-period exploits of "bootleggers" who produced moonshine or corn liquor, or whiskey, and the like. Both Kentucky bourbon and Tennessee whiskey variously make use of no less than 51 percent cornmeal mash. The primary distinction between mash and malt liquors is that mash is derived from corn-

## Fermented maize-based cereal products eaten in Latin America

Name	Description	Country
<i>Abati</i>	Alcoholic beverage produced from maize	Paraguay, Argentina
<i>Acupe</i>	Beverage produced from germinated maize that has been both fermented and sweetened	Venezuela
<i>Agua-agria</i>	Non-alcoholic beverage produced from ground maize and water.	Mexico
<i>Atole</i>	Non-alcoholic porridge produced from maize dough	Mexico
<i>Atole agrio</i>	Non-alcoholic porridge produced from black maize dough fermented 4 to 5 days	Mexico
<i>Cachiri</i>	Fermented beverage produced in clay pots from maize and manihot or fruit	Brazil
<i>Champuz</i>	Fermented beverage produced from maize or rice	Colombia, Peru
<i>Charagua</i>	Alcoholic beverage produced from pulque syrup, chili, and toasted maize leaves heated slowly and fermented.	Mexico
<i>Chica</i>	Alcoholic beverage produced from pineapple, barley steep liquor, and black maize dough. Beverage is fermented for 4 days, after which brown sugar, cinnamon, and cloves are added	Mexico
<i>Fubá</i>	Germinated maize grains fermented in water	Brazil
<i>Jamin-bang</i>	Bread produced from maize fermented for 3 to 6 days and cooked as a cake.	Brazil
<i>Napú</i>	Beverage consisting of germinated, ground, and fermented maize.	Peru
<i>Ostoche</i>	Alcoholic beverage concocted from maize juice and pulque or brown sugar	Mexico
<i>Pozol</i>	Non-alcoholic, albeit acidic, beverage produced as maize liquor. Balls of dough prepared from fermented masa are enveloped in banana leaves	Mexico
<i>Quebranta huesos</i>	Alcoholic beverage consisting of maize juice, toasted maize, and pirú fruits ( <i>Schinus molle</i> )	Mexico
<i>Sendechó</i>	Alcoholic beverage fermented from germinated maize and red chili. Maize dough is resuspended in water, boiled, bestowed, cooled, and inoculated with <i>Sendechó</i>	Mexico
<i>Sora</i>	Alcoholic beverage produced from germinated, ground, cooked and fermented maize	Peru
<i>Tepache</i>	Alcoholic beverage fermented from maize grains, brown sugar, and water.	Mexico
<i>Tesgüino</i>	Alcoholic beverage produced from germinated maize, both ground and cooked with fragments of plants that serve as enzyme sources	Mexico
<i>Tocos</i>	Dessert produced from maize fermented for 2 to 3 months and then cooked.	Peru
<i>Zarzaparrilla bark wine</i>	Alcoholic beverage consisting of maize beer and zarzaparrilla bark	Mexico

meal made from ground and unsprouted maize kernels, whereas the malt liquors make use of cornmeal ground from sprouted and dried maize kernels. Betty Fussell provides a detailed overview of the history and culture of moonshine, as well as first-hand accounts concerning the methods, ingredients, participants, and paraphernalia involved in bootlegging (pp. 252–264).

### The Globalization of Maize

Although the United States is the leading maize producer in the world, maize remains the primary staple for much of Latin America, which is why that region is the leading consumer of maize as a food for humans (as opposed to its consumption as a fodder for livestock and poultry). Since the days of its earliest evolution and domestication in Mexico, maize has been adopted as a primary staple or supplement in virtually every world region. Thus it has become the stuff of cross-cultural traditions and, more often than not, has taken center stage as the primordial embodiment of myth, ritual, legend, folklore, and ultimately multinational commerce and globalization. Apart from its many traditional uses and its consumption as whole maize kernels or as corn-on-the-cob, maize is key to an incredible variety of foods and products. One need only review Diane Kennedy's *The Cuisines of Mexico* to recognize the totality and dominance of maize and its by-products in the whole of Mexican cuisine. Similarly, any superficial review of Julia Child's recipes in her book *The Way to Cook* will provide an encyclopedic retrospective on the place of maize as culinary ingredient and staple foodstuff in the most popular and trendy of American and international favorites.

**MALNUTRITION.** Malnutrition results from the chronic dietary intake of nutrients or energy that provides considerably less or more than is required to be considered adequate or appropriate to support the everyday needs of the human body. Such adverse nutrient intakes are detrimental to human health and may lead to a state of deficiency, dependency, toxicity, or obesity. Malnutrition includes undernutrition, which means the body is not receiving nearly enough nutrients, and overnutrition, which means the intake of nutrients is grossly excessive.

### Undernutrition

Undernutrition continues to be a significant cause of malnutrition in developing countries, although it is relatively

rare in developed countries. Poverty in developing countries contributes more to undernutrition than a lack of global food production and is considered the chief cause of malnutrition. Families that are poor do not have the economic, social, or environmental resources to purchase or produce enough food. Poor soil conditions may also contribute to a family's inability to grow enough food to prevent malnutrition and the accompanying complications to health. Additionally, for the urban poor, low wages, underemployment, and food prices beyond the reach of families also contribute to undernutrition.

Prolonged dietary intakes deficient in energy or calories, protein, fat, vitamins, and minerals lead to illness and eventually death if not corrected. Undernutrition may also be the result of psychological disorders, such as anorexia nervosa, which manifests as an unwillingness to eat enough food to sustain life. Elderly adults often have a decrease both in appetite and intestinal function and are at an increased risk for undernutrition. Children, particularly infants and those under five years of age are also at an increased risk for undernutrition due to a greater need for energy and nutrients during periods of rapid growth and development. Infants born to undernourished mothers are more likely to be low birth weight infants. Addiction to alcohol or drugs may also lead to undernutrition when the addicted individuals favor alcohol and/or drug intake over adequate food intake. Severe, prolonged diarrhea, renal failure, infection, or diseases that cause the malabsorption of nutrients in the small intestine also may cause undernutrition even if dietary intake is adequate. It is obvious that the causes of undernutrition are varied and complex, requiring solutions that may also be complex.

### **Nutrients Required to Prevent Undernutrition**

The nutrients required in adequate amounts by the body to prevent undernutrition are carbohydrates, fat or lipids, protein, vitamins, minerals, and water. Carbohydrates provide the body with energy (about 4 kilocalories per gram of carbohydrate consumed). Carbohydrates also protect protein stores in the body. A minimal intake of 50 to 100 grams (1.8 to 3.5 oz.) of carbohydrates is required to prevent the development of ketones that the brain can use somewhat inefficiently for energy. The brain optimally uses carbohydrate for energy, but when carbohydrate intake is inadequate for several weeks, the body does not metabolize fatty acids completely in order to produce ketones for energy. In addition to ketone formation resulting from insufficient carbohydrate consumption, body protein will also be lost, and the body will generally become weakened.

Fats or lipids provide essential fatty acids upon metabolism following consumption. Essential fatty acids are obtained from dietary lipids and are termed essential because the human body cannot synthesize them. Essential fatty acids are important for human health because they participate in immune processes, vision, are an integral

part of cell structures, and participate in hormone-like compound production. If an inadequate intake of lipids is routinely consumed, the body becomes deficient in essential fatty acids. This results in skin problems, diarrhea, and an increase in infections with a corresponding decrease in the ability of the body to heal wounds. Lipids also provide energy for the body (about 9 kilocalories per gram (28 kilocalories per ounce of fat consumed), can be stored for future use as energy, insulate the body and protect body organs, and aid in the absorption and transport of fat-soluble vitamins (vitamins A, D, E, and K) throughout the body. The fat-soluble vitamins are important for vision (vitamin A), bone metabolism (vitamin D), providing antioxidant protection from free radicals (vitamin E), and blood coagulation (vitamin K), among other functions.

Protein is a very important nutrient because so many substances in the body are made from it. Proteins are made when amino acids are combined in specific sequences to form specific proteins. The sequence of the amino acids determines the shape of the protein, and the shape of the protein, in turn, determines the function of the protein. Amino acids can be obtained from plant or animal sources. There are nine essential amino acids: histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, and valine. The human body is not able to synthesize these amino acids, so they must be derived from the foods we eat. There are eleven nonessential amino acids that the human body is able to make: alanine, arginine, asparagine, aspartic acid, cysteine, glutamic acid, glutamine, glycine, proline, serine, and tyrosine. As stated previously, amino acids are necessary for protein synthesis, but they are also important because they provide the body with a special form of nitrogen that the body cannot get from carbohydrates or lipids. Protein, like carbohydrate, provides approximately 4 kilocalories per gram of protein consumed, but requires much more metabolizing and processing by the liver and kidneys to put the energy from protein to use. Protein is a part of every cell in the human body. Blood proteins enable the body to maintain the right balance of fluid inside and outside of cells. When adequate protein is not consumed, there is a lower concentration of blood proteins in the bloodstream, which causes the balance of fluids inside and outside of cells in tissues to be thrown off, resulting in swelling of tissues or edema, which can lead to serious medical problems. Proteins also help regulate the pH, or acid-base balance, in the blood, are necessary for the synthesis of many hormones and enzymes, and participate in important cell formation for cells vital for the immune system. Amino acids from protein can also be used to produce glucose, which is a positive thing for providing glucose after an overnight fast. But in the case of starvation, excessive muscle tissue is wasted and results in diminished health. Protein-energy malnutrition results from near starvation and may be seen in the body tissues in either a wet, dry, or combined form. The dry form, marasmus, is caused by deficiency of protein and non-

protein nutrients, with the individual being very thin from the loss of muscle and body fat. The wet form, kwashiorkor, is caused primarily by protein deficiency, with energy deficiency being secondary, and is accompanied by edema. The combined form, marasmic kwashiorkor, results from protein and energy deficiency with edema and more body fat than is seen in marasmus.

There are also water-soluble vitamins in addition to the fat-soluble vitamins. Because water-soluble vitamins are not stored in any appreciable amounts in the body, but are excreted readily in urine, it is relatively easy to become depleted of them. Fat-soluble, in contrast, are stored in adipose tissue and the liver, and consequently it is more difficult to become deficient of them. The water-soluble vitamins are the B vitamins and vitamin C. The B vitamins are thiamin, riboflavin, niacin, pantothenic acid, biotin, pyridoxine, folate, and vitamin B<sub>12</sub>. All of the water-soluble vitamins except vitamin C have coenzyme functions and are involved in a variety of reactions including energy metabolism, DNA synthesis, nerve function, protein and carbohydrate metabolism, and fat synthesis. Vitamin C is involved in protecting the body from oxidative damage caused by substances called free radicals. It also functions in connective tissue synthesis, hormone synthesis, and neurotransmitter synthesis. Physiological consequences of deficiency include inflammation of the mouth and tongue (riboflavin deficiency); diarrhea, dermatitis (niacin deficiency); edema, weakness (thiamin deficiency); tongue soreness, anemia (biotin deficiency); fatigue, tingling in hands (pantothenic acid deficiency); poor growth, inflammation of the tongue (folate deficiency); poor nerve function, macrocytic anemia (vitamin B<sub>12</sub> deficiency); and poor wound healing, bleeding gums (vitamin C deficiency).

Minerals are important nutrients that must be obtained from foods consumed, as the human body is unable to synthesize them. Some factors that influence mineral bioavailability (the extent to which minerals in food consumed is available for the body to put to use) are the amount of mineral content in the soil in which the food providing the mineral was grown; dietary fiber consumed in the same meal as a food containing the minerals; mineral-mineral interactions; and vitamin-mineral interactions. Sodium, potassium, chloride, calcium, phosphorus, magnesium, and sulfur are the major minerals. Deficiencies of these minerals lead to such symptoms as muscle cramps (sodium), irregular heartbeat (potassium), convulsions in infants (chloride), an increased risk for osteoporosis (calcium), diminished bone support (phosphorus), and poor heart function (magnesium). There are also so-called trace minerals that are only required in very small amounts to contribute to optimal health. These trace minerals are iron, zinc, selenium, iodide, copper, fluoride, chromium, manganese, and molybdenum. When inadequate amounts of foods containing the trace minerals are consumed, symptoms begin to appear. These symptoms include low blood iron (iron), skin rash/poor

growth and development (zinc), muscle weakness (selenium), goiter (iodide), anemia/poor growth (copper), increased risk for dental cavities (fluoride), and high blood glucose after eating (chromium).

Developed countries typically have water supplies that are monitored for safety by government agencies and are provided in large enough quantities that a lack of drinking water is not the norm. Developing countries, however, may not have water that is free from contamination, or because of drought or other natural disasters do not have a large enough water supply for human consumption or to provide water for livestock or crops. Water is vital for life and, without it, an adult can survive only a few days because the human body does not have the ability to store water. Water is found inside of cells as intracellular fluid and outside of cells as extracellular fluid. A proper balance between intracellular and extracellular water is necessary to prevent complications such as edema. Water also is responsible for regulating body temperature, most notably through the cooling-off process accomplished by perspiration. Water is necessary to provide lubrication for joints such as the knees. Without adequate water in the form of amniotic fluid in the womb of a pregnant woman, the growing fetus does not have sufficient support to prevent injury should the mother fall or be otherwise jarred abruptly. Water is also the primary avenue utilized by the body to rid itself of waste products. While water does not supply energy as carbohydrates, protein, and fats are able to do, it is still a very important nutrient necessary to prevent malnutrition.

### Overnutrition

Overnutrition results when energy expenditure is grossly exceeded by energy intake and leads to overweight and obesity. Developed countries, with their abundant food supplies and processed foods, are most afflicted with overnutrition and the medical complications associated with it. Due to the excessive intake of food products, the amount of fat-soluble vitamins and minerals in the body can rise to toxic levels because they are stored in the body. Developed countries have greater incidences of cardiovascular disease, blood lipids, diabetes mellitus, hypertension, respiratory problems, gallbladder disease, arthritis, and cancer, all of which are connected to complications stemming directly from overnutrition.

### Methods of Evaluating Malnutrition

Malnutrition is diagnosed based on the findings of a medical and diet history, physical examination, and laboratory tests. The results are then compared with norms of weight for height, body mass index (body weight in kilograms divided by height in meters squared), dietary intake, physical findings, and plasma levels of nutrients and nutrient-dependent substances such as hemoglobin. The physical examination would necessarily include anthropometric measurements, as well as close examination of the skin, hair, and mouth for symptoms of malnutrition.

For example, depigmentation of the hair is indicative of undernutrition, and a body weight that is 20 percent above the average desirable body weight as determined by insurance company standardized charts would indicate overnutrition. A triceps skinfold test may be utilized to determine the body's energy stores. Laboratory tests are used to reveal the extent to which amino acid nutrition is meeting the body's needs to determine undernutrition, or plasma lipids in the diagnosis of overnutrition. In the field when assessing nutritional status, the medical and diet history and physical examination may be the only tools accessible to the physician or nurse, particularly in developing countries.

### **Who is at Increased Risk for Malnutrition?**

The risk for malnutrition is increased for a variety of reasons. Increased nutritional needs during growth, pregnancy, lactation, old age, infection, certain cancer therapies, or immune deficiency disorders increase the risk of malnutrition. Diets that focus on a narrow range of foods may not provide the variety of nutrients required and lead to deficiencies. Those experiencing famine, with the accompanying reduction in available food, are at great risk for malnutrition in the form of undernutrition. Lack of money to purchase an adequate diet or cultural practices that dictate which members in the family get a large or small amount of food may also lead to malnutrition. Any medical condition that effects the absorption of nutrients from foods, or requires medication that has adverse consequences on appetite, may cause malnutrition if the condition is long term. Taking megadoses of vitamin/mineral supplements may result in toxic levels of the substances taken in the body with the outcome being a state of overnutrition.

### **Correcting Malnutrition in the United States**

Since the Great Depression of the 1930s, the federal government of the United States has undertaken the task of alleviating and/or preventing malnutrition. In the 1960s, President John F. Kennedy reestablished the federal government's efforts to end debilitating hunger. Individuals and families who have low incomes may take advantage of several federally sponsored programs to ensure a better quality of nutrient intake. Food stamps are available to those who are usually employed but having difficulty purchasing an adequate food supply by using coupons to purchase food from grocery stores. The Commodity Supplemental Food Program distributes U. S. Department of Agriculture surplus foods through county agencies to such low-income populations as pregnant women and families with young children. The School Lunch and Breakfast Programs offer free or reduced-priced meals based on the Food Guide Pyramid to children of low-income families, with the cost of the reduced-priced meals being based on family income. The Summer Food Service Program offers free, nutritious meals and snacks to low-income children and distributes the meals from

a central location during lower and secondary school vacations. There are also programs targeted specifically at different age groups. Preschool children enrolled in organized child-care programs receive meals at no cost, and the child-care program receives reimbursement for the meals through participation in the Child-Care Food Program. For individuals 60 years or older, a free noon meal is provided at centralized sites as part of the Congregate Meals for the Elderly Program. Homebound individuals over 60 years of age can take advantage of home-delivered meals at no cost or for a fee, depending on income, at least five days per week.

### **World Hunger: Addressing a Global Problem**

In 1798 the English clergyman and political economist Thomas Malthus suggested that the world's population was growing at a rate faster than the food supply. The year 2002 finds world population growth exceeding economic growth, and poverty on the rise. Globally less than one-half of 1 percent of the world's yearly production of goods and services goes exclusively to economic development assistance, yet 6 percent goes to support the world's military operations. Civil wars in some countries have substantially retarded progress of the poor and continue to contribute to massive undernutrition. Environmental factors such as soil erosion or lack of fresh water for irrigation of crops exacerbate the problem of providing sufficient quantities of foods for many countries. What is being done to overcome all of these detriments to feeding the world's hungry? Since the 1960s, an American program, the Peace Corps, has been instrumental in providing education, distributing food and medical supplies, and building structures for locals to use in developing nations. National surveys such as the National Family Health Survey conducted in India are valuable tools in the determination of whether any progress is being made to improve the nutritional status of the nation. Advances in biotechnology to genetically alter plants and animals to improve the nutritive quality of the foods produced from them may help to meet increasing food needs both now and in the future. The United Nations and the World Health Organization cry out for governments in developed countries to facilitate greater strides in improvements in malnutrition in undeveloped countries by financial, educational, and scientific interventions. What will be required to eradicate malnutrition in this world is a coming together of the leaders of rich and poor nations to the same degree. Globally, there is an adequate food supply and the technical expertise necessary to address the problems and complications of malnutrition. All that is lacking is the political cooperation to address this devastating situation.

## MALNUTRITION: PROTEIN-ENERGY

**MALNUTRITION.** Protein-energy malnutrition (PEM) may be present at any time during the life cycle, but it is more common in the extreme ages, that is, during infancy/childhood and in the elderly. The present review will be restricted mostly to the condition present during infancy and childhood.

Protein-energy malnutrition is a syndrome characterized by its progressive onset and a series of symptoms and signs that encompass a continuum, ranging from clinically undetected manifestations to the full-blown clinical picture of marasmus or kwashiorkor. A syndrome is defined in clinical practice as a set of symptoms and signs that may be caused by different etiologies.

In the case of PEM, the earliest symptoms include subtle changes in the mood of the child, which may be described by the mother as saying that the child is not as playful as he/she used to be. Further changes include a loss of appetite and a loss of interest in the surroundings, which lead to decreased social interaction with peers or siblings and adults (parents or other caregivers). When PEM becomes more severe, there are adverse effects on the child's cognitive and behavioral development, evident in both the short and the long term.

In relation to signs, the earliest clinical sign of PEM is the lack of adequate weight gain. Also common in the early stages are mild episodes of common acute infectious diseases, such as acute diarrhea or acute respiratory infections. As the condition advances, the child will show signs of body wasting, progressing to an extreme thinness. If the syndrome becomes chronic, there are small or no increases in length. When the condition becomes more severe, the child may show the clinical pictures of marasmus or kwashiorkor, which will be defined later in this article.

The etiology of protein-energy malnutrition as a syndrome may be classified as primary or secondary. Although in practice most cases of PEM are caused by a combination of both, the concept may be useful for targeting interventions. Primary PEM refers to a deficit of available food. This, in turn, may be because of biological conditions, such as maternal malnutrition prior to or during pregnancy and lactation, or to social conditions, such as poverty; to a limited or selective unavailability of food; to war; to ecological disasters leading to famine, or, more often, as a result of profound social inequalities, either at the individual level (discrimination, refugees, prisoners) or at the community or country level. The largest prevalences of protein-energy malnutrition are found in

socioeconomically deprived areas of the world, as will be reviewed further on in this article. Secondary causes of PEM include several conditions that impair food intake, absorption, or utilization, or that increase energy and/or protein requirements or losses. Secondary causes of PEM may be biological or social conditions.

Biological conditions may interfere with food intake, such as congenital anomalies (for example, harelip); with absorption, such as any of several malabsorption syndromes (for example, tropical sprue); or with utilization, such as inherited metabolic diseases (for example, phenylketonuria). Biological conditions that increase the need for energy include all infectious diseases accompanied by fever, and other diseases that increase catabolism, such as tuberculosis, or that are accompanied by an increased nutrient loss, such as intestinal parasitism.

On the other hand, social causes that affect food intake, whether it be in quantity or quality (protein-energy or micronutrient content), include several conditions associated with poverty, such as ignorance, inadequate weaning practices, child abuse, alcoholism or other drug addictions, and others.

Different conceptual frameworks for the study of malnutrition have been proposed and adopted throughout the years; one of the most widely accepted ones was developed during the WHO/UNICEF Joint Nutrition Programme in Iringa, Tanzania (B. Jonsson et al., 1993) (UNICEF 1990), from where it has been extended to many parts of the world. An appealing feature of this conceptual framework is that it may be adapted to describe causes of the major nutritional deficiencies present in the world, including vitamin A, iron, and iodine deficiency.

### **Clinical Picture of Marasmus and Kwashiorkor**

Marasmus is characterized by a chronic and severe restriction of both energy and protein to the body. Marasmus is more frequently found at a younger age than kwashiorkor, usually in children under one year of age. A marasmic child presents severe wasting, with a very low weight-for-age and reduced length-for-age, often below  $-3$  standard deviation of the reference population values. The clinical history of a marasmic child may reveal poverty or famine affecting the family; inadequate child-rearing practices, like starvation wrongly prescribed as part of the management of diarrhea; an early stopping of breast-feeding; over-dilution of formula; a history of repeated and/or chronic infections, such as diarrhea or tuberculosis; or some physical condition that affected the child's growth and development, such as prematurity, mental defects, or a malabsorption syndrome. The mother or caregiver will often report that the child is hungry. On a first appreciation, the child may be interested in the environment, with an active cry and reaching for food if offered, or else he/she may be depressed to the point of coma. The typical clinical picture is that of a striking loss of subcutaneous fat and muscle wasting, observed as markedly thin limbs, an evident rib cage,

sunken cheeks and eyes that give the child a "monkey-like" or gaunt appearance, a prominent abdomen (although with no evidence of an enlarged liver), and a relatively big head. The hair is often thin and dry, and comes off easily. However, skin rashes or dermatosis are not usually present. Common micronutrient deficiencies include vitamins A and D, zinc, and iron, although anemia is less common in marasmus than in kwashiorkor.

The clinical picture of kwashiorkor is not as striking in appearance, as this syndrome often affects slightly older children, i.e., between one and three years of age. The clinical onset of kwashiorkor usually takes place in a shorter period of time as compared to marasmus, and is characterized by a relative, though severe, limitation in protein intake, with a lesser involvement of energy deficit. A child affected with kwashiorkor is often apathetic to external stimuli, is irritable, and gives the impression of misery, rejecting or crying when cared for. The most salient clinical characteristic of this syndrome is the presence of edema, which may mask the evidence of body weight loss and reduced length in relation to age. It is also common to find skin lesions that range from a flaky, pink dermatosis with skin dryness and depigmentation to deep ulcerations. Also common are petechiae and ecchymoses, as well as clinical signs of anemia. The hair presents discoloration with bands of dark and light hair (described by clinicians as the "flag sign"). An enlarged, fatty liver is also characteristic of kwashiorkor, palpable as a soft mass under the right rib cage. Co-occurring micronutrient deficiencies are common, so clinical signs of deficiencies of specific vitamins, including A, B, C, D, iron, or others, also may be present.

### **Classification of Protein-Energy Malnutrition**

The clinical signs of severe PEM are so impressive that, for several years, they drew the attention of pediatricians and other physicians interested in furthering the understanding of the clinical syndromes and their treatment. Therefore, the study of PEM was long confined to the hospital setting. Actually, the first classification of PEM came from Mexican observers, who ranked the severity of malnutrition based on the risk of death for children with a clinical diagnosis of PEM. This group, led by Gomez, proposed that children with a weight-for-age deficit greater than 40 percent in relation to a reference population were in the greatest risk of dying, and thus labeled them as having third-degree malnutrition. Further, children with 25–40 percent weight-for-age deficit were labeled as having second degree malnutrition, and children with 10–25 percent weight-for-age deficit were classified as having first degree malnutrition (Gómez-Santos, 1946).

This classification had a high predictive value for the risk of death, and therefore had important implications for clinical practice. It was further abused, however, when its use was extended to the classification of malnutrition at a population level. In other words, children with no

evidence of clinical malnutrition who have low weight-for-age should not be classified as malnourished; doing so may not only misdiagnose an individual, but may overestimate the prevalence of malnutrition in a population. Also, the Gomez classification has been criticized because a single measure of a child's weight referred to age gives no idea about the nutritional history of the child. That is, an underweight child may be growing according to his/her normal growth channel, may be recovering from a recent episode of weight loss ("catch-up growth"), or may be deteriorating in relation to the recent past.

In order to overcome these caveats, Waterlow proposed combining weight-for-height, as an indicator of an acute episode of malnutrition, with height-for-age, as an indicator of chronic nutritional deficits that would be reflected in growth stunting (Waterlow, 1972).

Although these classifications have been used for several years, they have two important disadvantages that often are overlooked. To illustrate the first disadvantage, it is important to highlight the concept of Z-scores as a means of describing an individual child's anthropometric indicators in a normal distribution. The normal distribution of a reference population has been published by the World Health Organization (WHO) and is most often accepted worldwide as the standard for comparison. Eighty percent of the median weight-for-age might be above or below  $-2$  Z-scores, depending on the child's age. The second disadvantage is that, to approximate a fixed point in the normal distribution, say,  $-2$  Z-score, different percents of median have to be used depending on the anthropometric index used—for example, 90 percent for low height-for-age, or 80 percent of low weight-for-height.

In consequence, the World Health Organization Expert Committee on Physical Status has recommended the use of Z-scores to express weight-for-age, weight-for-height, or height-for-age relative to values reported in a reference population (WHO Expert Committee on Physical Status, 1995). The use of this system has several advantages; i.e., when applied at a population level, it allows the mean and standard deviation to be calculated for a group of Z-scores, and it allows the use of fixed cut-off points (i.e.,  $-1$ ,  $-2$ , or  $-3$  Z-scores) to classify mild, moderate, or severe deficits for any anthropometric indicator. Although the use of Z-scores may be difficult to grasp for those who have been accustomed to classifying nutritional deficits based on the percent of median, the advantages of Z-scores outweigh their disadvantages.

### Global Prevalence of Protein-Energy Malnutrition

The most recent estimates about the distribution of PEM at a worldwide level were compiled by the World Health Organization (WHO) Programme of Nutrition, available in its Global Database on Child Growth and Malnutrition (de Onis and Blössner, 1997). This database covered 95 percent of the total population of children under 5 years of age who lived in 103 developing nations in 1995,

as was reported in nationally representative surveys available at the time. According to these data, an estimated 206.2 million children, who represent 38 percent of all children under 5 years old, were stunted (low height-for-age); 167.3 million children (31 percent) were underweight (low weight-for-age), and 48.8 million children (9 percent) were wasted (low weight-for-height). PEM is most often found in the poor regions known as the "developing world." The largest number of affected children were found in Asia, where 41 percent of all under 5 years old were stunted, 35 percent were underweight, and 10.3 percent were wasted. Africa had 38.6 percent stunted, 28.4 percent underweight, and 8 percent wasted children of all those under 5 years old; Latin America and the Caribbean showed 17.9 percent stunted, 9.5 percent underweight, and 3 percent wasted children of all those under 5 years old. The proportion of children under 5 years of age affected in Oceania was 31.4 percent, 22.8 percent, and 5 percent, respectively, but the total number of children living in this region is much lower, so in reality, these percentages translate into many fewer children affected than in the other regions.

Since the mid-1980s, the Administrative Committee on Coordination/Sub-Committee on Nutrition (ACC/SCN) of the United Nations periodically has examined the trends of malnutrition in the world's children. In its Third Report on the World Nutrition Situation (ACC/SCN, 1997), this Committee (from data from 61 countries) estimated the trends in stunting with two or more nationally representative surveys. In the period from 1980 to 1995, stunting declined globally at a rate of 0.54 percentage points per year. Sub-Saharan Africa had an increase of 0.130 percentage points per year in the average prevalence of stunting; the remaining regions of the world showed statistically significant decreases that ranged from  $-0.26$  in Middle-America and the Caribbean to  $-0.90$  in Southeast Asia (Table 1).

The same Committee was able to use data from 95 countries that had data from at least one national survey to estimate the prevalence of undernutrition; underweight and stunting showed a consistent 11.5 percentage point difference. The higher prevalence was for the underweight classification. During the 1980–1995 period studied, only sub-Saharan Africa had an increase in the prevalences of both stunting and underweight; all the other regions showed decreasing trends in these two indicators (Table 1).

### Acute and Long-Term Consequences of Protein-Energy Malnutrition

PEM results from a relative deficiency of protein (essential amino acids and/or total nitrogen) and energy substrates (carbohydrates, fats, or proteins). However, these deficiencies are almost always accompanied by micronutrient (minerals and vitamins) deficits. Manifestations of PEM differ depending on the duration, the severity, and the combination of these deficiencies. In the early stages,

TABLE 1

**Estimated prevalence of stunting (%) and numbers of children affected for 1980, 1985, 1990, and 1995 and by region**

Region	Prevalence stunting				Numbers stunted (in millions)				% Increase/ decrease in numbers from 1980 to 1985
	1980	1985	1990	1995	1980	1985	1990	1995	
Sub-Saharan Africa	37.4	38.1	38.7	39.4	26.255	30.832	36.248	42.590	+62
Near East/North Africa	30.8	25.9	23.0	22.2	11.397	10.991	10.865	10.913	-4
South Asia	66.1	61.9	57.7	53.5	88.873	93.237	91.520	89.877	+1
South East Asia	51.9	47.3	42.8	38.3	35.581	32.862	30.119	30.206	-15
Middle America/Caribbean	31.6	30.4	29.1	27.8	5.398	5.467	5.631	5.626	+4
South America	25.0	21.0	16.9	12.9	8.285	7.309	5.965	4.644	-44
China(1982)			31.4				36.068		
Across all regions (excluding China)	48.8	45.6	42.5	39.9	175.789	180.698	180.348	183.856	+5

Note: These estimates were derived assuming a linear relationship between stunting and year. The only region for which there was evidence of a nonlinear relationship was Near East/North Africa. For this region, a quadratic model was used to approximate the nonlinear relationship. The estimated prevalence values for this region were from this model.

there are functional impairments, which are later followed by biochemical and physical damage.

The identification, understanding, and treatment of the full-blown clinical syndromes characteristic of severe PEM began in the mid-1930s with the description of kwashiorkor (Williams, 1933). On the other hand, the identification and understanding of the functional manifestations of malnutrition have only come about during the last three decades of the twentieth century, with the launching of two large-scale, community-based research projects: the first one, known as the INCAP Longitudinal Study, was based in Guatemala (Habicht and Martorell, 1992). The second took place simultaneously in three countries—Egypt, Kenya, and Mexico—and was known as the CRSP study (Calloway, Murphy, et al., 1988).

**Functional consequences of protein-energy malnutrition.** As described earlier, the functional consequences of PEM were recognized and studied only relatively recently (Allen, 1993). Among the most well documented functional consequences of PEM are growth impairment, a reduced immune response, and a disruption in cognitive ability.

**Growth impairment.** Growth failure because of PEM usually starts to manifest very early in life. Information from the INCAP longitudinal study, as well as from the CRSP studies, coincides in showing that growth stunting begins at about 3 to 4 months of age and is complete before 18 months (Allen, 1995). A further contribution from the INCAP study was provided by a long-term follow-up of the same populations that showed not only that growth stunting present during infancy carried on until adolescence, but also that length at 3 years of age was a strong predictor of adolescent size (Martorell, Schroeder, et al., 1995). It also seems as if stunting in

early life is correlated significantly with reduced physical performance (Haas, Martinez, et al., 1995) and reduced psychomotor and mental performance, both during late childhood (Mendez and Adair, 1999) and even until adolescence (Grantham-McGregor, 1995; Pollit, Gorman, et al., 1995).

Two more relevant issues related to growth failure are that there is a window of opportunity for intervention from the ages of 3 to 6 months, when response to the intervention may be greatest (Lutter, Mora, et al., 1990), and that most of the growth deficit found at later ages accumulated during the first months of life (Rivera, Cortes, et al., 1998).

**Immune response.** It has been recognized that malnutrition is the most common cause of immunodeficiency worldwide (Chandra, 1991). Actually, malnutrition and infection interact in a vicious cycle: the presence of one more easily leads to the development of the other (Scrimshaw, Taylor, et al., 1968). There are several mechanisms involved in this relationship. PEM impairs cell-mediated immunity, phagocytic function, and the complement system. It also diminishes immunoglobulin (IgA, IgM, and IgG) concentrations, and cytokine production (Chandra, 1991). Micronutrient deficiencies associated with PEM also adversely effect the immune response. For example, iron plays an important role in several metabolic functions, including both the host and invasive bacteria. Several microorganisms that infect the human body only achieve their full infectious activity in the presence of iron. Such is the case of bacteria that cause diarrheal disease, such as *Escherichia coli*, *Yersinia septica*, *Salmonella sp.*, and *Vibrio cholerae*; and others responsible for lower respiratory infections, such as *Mycobacterium tuberculosis*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, and *Listeria monocytogenes*. These microorganisms actively seek iron in their host during infection, uptaking it from destroyed

## THE IMPORTANCE OF MARGINAL MALNUTRITION

The borderline between normal nutrition and malnutrition is so thin that, in clinical practice, there is no fool-proof way to distinguish them. This is at least one of the reasons why so little attention was given to marginal malnutrition (i.e., malnutrition that borders normal limits). A further reason, though, obeyed a misconstruct that prevailed for a long time; that is, that only children with severe malnutrition had an increased risk of dying. This concept was probably triggered by the initial clinical observations on the increased risk of death in hospitalized children with third degree malnutrition (Gomez, Ramos-Galvan, et al., 1956), and was reinforced further by epidemiological observations in the field.

In a classic study, Chen and colleagues reported their findings on 2,019 Bangladeshi children between the ages of 13 and 23 months, who were followed for a period of 24 months, assessing death rate (Chen, Chowdhury, et al., 1980). The study team had precise information on the age of these children and had performed a cross-sectional nutritional assessment at baseline. Further, a demographic surveillance team identified all deaths occurring during the study period, recording age and probable cause of death. Child mortality rates were analyzed stratifying by percentage weight-for-age, weight-for-height, and height-for-age. The authors found that severely malnourished children experienced about a twofold higher mortality risk over the first twelve months of the study, and fourfold during the second twelve months of the study, as compared to normally nourished and mildly and moderately malnourished children, who shared the same level of mortality risk. The nutritional index with the strongest discriminative power to identify risk of death was weight-for-age.

This article, and others that followed in the literature (Trowbridge and Sommer, 1981; Heywood, 1982; Bairagi, Chowdhury, et al., 1985), seemed to find a threshold effect for mortality at the cutoff corresponding to third-degree malnutrition, below which the risk of death increased sharply. It was not until 1993 that Pelletier, Frongillo, and Habicht questioned this model (Pelletier, Frongillo, et al., 1993). Following their reasoning, the threshold effect reflects a model in which a popula-

tion's mortality rate increases as a linear function of malnutrition.

An alternative model is a quadratic one that accounts for the sharp increase in mortality found beyond the threshold. Pelletier et al., however, sustained that a synergistic or multiplicative model, in accordance with the clinical observations that child mortality is a function of the adverse synergism between malnutrition and morbidity (Scrimshaw 1970), provides a much better explanation of the relationship. When testing their multiplicative (i.e., synergistic or exponential) model on a set of available data from several large-scale population studies, they found that an exponential model fit the available data best. Based on the best fit of the exponential model, they calculated that the odds of dying increased at a compound rate of 7.3 percent for each percentage point deterioration in weight-for-age.

In summary, these authors provided strong evidence that a threshold effect does not exist. Their model is consistent with the view that because of the greater number of affected children, mild to moderate malnutrition is associated with a greater absolute risk of dying. The policy implications of this conclusion are striking. Considering that the majority of malnourished children fall in the mild to moderate category, and that their risk of dying is higher than that of non-malnourished children, the attention of health-care programs should be immediately drawn to this population.

Certainly, a larger number of childhood deaths would be prevented if efforts were directed to improve the nutritional status of this group and to lower morbidity burden of all malnourished children, and not just for the ones who are in the worst condition. Therefore, the authors estimate that 45 percent to 83 percent of all malnutrition-related deaths occur in children who present mild to moderate malnutrition, a group that is usually excluded from direct interventions based on the impression that their risk of dying is small. Also, it highlights that either reducing morbidity or reducing malnutrition would reduce child mortality, but a much larger effect (actually, a synergistic effect) would be achieved if both conditions were addressed simultaneously (Pelletier, 1994).

red cells (erythrocytes) and body stores (liver). On the other hand, the host tries to make iron less available to invasive microorganisms, sequestering it through different mechanisms—referred to as nutritional immunity—that include the binding of iron to transferrin and lactoferrin, and the increase in ferritin saturation in the liver (Kochan, 1976). Other micronutrients that play ac-

tive roles in modulating immunity include zinc, selenium, copper, vitamins A, C, E, B<sub>6</sub>, and folic acid (Nezu and Nakahara, 1994).

Conversely, infectious diseases lead to malnutrition by several mechanisms that often interact with each other. Almost every malnourished child will sooner or

later present with diarrhea. Many of the interactions between malnutrition and infection are understood because of studies of diarrheal disease (Chen, 1983); hence the illustration of the mechanisms by which these two morbid conditions interact is particularly useful. One of the first symptoms of diarrheal disease is anorexia, as a result of vomiting and abdominal discomfort. Also, fever, dehydration, and electrolyte imbalances contribute to it (Martorell, Yarbrough, et al., 1980). Anorexia leads to a restricted intake, which is often reinforced by erroneous caregiver practices. In part, it is culturally engrained in different societies to withhold food from a diarrhea-affected child (Bentley, 1988), and it is also quite common to find physicians who still think that it is necessary to “put the bowel to rest” during the acute stage of the illness (Brown and MacLean, 1984). The deleterious effect of decreased food intake is worsened by increased catabolic losses of nitrogen that occur as a result of increased metabolic rates and structural damage to the intestine (Powanda, 1977). Another consequence of intestinal damage is the transient loss of absorptive surface and absorptive function as a result of villous atrophy (Davidson and Barnes, 1979). This condition leads to a decreased absorption of macronutrients (fat and carbohydrates) and micronutrients (particularly fat-soluble vitamins). The presence of unabsorbed carbohydrates in the intestinal lumen increases the osmolarity of the intestinal content, thus causing an hyperosmolar diarrhea (Wapnir, 1982). It also subjects these substrates to bacterial fermentation, which produces gas and intestinal bloating, worsening gastrointestinal symptoms. Catabolic losses also are increased by the presence of fever. In cases of parasitic infestations, the child’s nutritional status is impaired by blood losses that are secondary to colitis or direct intestinal mucosal damage (common in cases of roundworm [*Ascaris lumbricoides*], hookworm [*Ancylostoma duodenale* and *Necator americanus*], or whipworm [*Trichuris trichiura*]). Parasitic infestations also are associated with respiratory symptoms (particularly in case of *Ascaris* infestations) and anorexia (Lunn and Northrop-Clewes, 1993).

*Disrupted cognition.* PEM can disrupt cognition in several ways. Following the lessons learned from the effect of PEM on the body during infections, the classic explanation was that malnutrition caused physical damage to the brain, particularly during sensitive periods of development, namely, during the first two years of life, when about 80 percent of the brain’s growth is achieved (Guilarte, 1993; Levitsky and Strupp, 1995). At present, however, it is clear that there are several other mechanisms, aside from organic damage, by which malnutrition can impair intellectual development. There is also evidence that at least part of this damage may be reversible, even in the presence of structural damage to the brain (Levitsky and Strupp, 1995).

Malnutrition may affect brain growth and development, which will be reflected in cognitive disabilities, mo-

tor impairment, or lower intelligent quotient (IQ), by means of micronutrient deficiencies such as vitamin B<sub>6</sub> or iron, both of which are vital for normal brain function (Guilarte, 1993; Pollitt, 1997). Malnutrition also may affect these functions because of energy deficiency, which limits activity and social interaction with peers and caregivers. This mechanism was explored first in the early 1970s by Levitsky and coworkers in a rat model. They showed that energy-deprived rats scored lower on such tests as maze running—a proxy for mental ability—because they were so feeble that they withdrew from contact with their peers and the objects in their surroundings (Levitsky and Strupp, 1995). Similar findings were shown to be present in children living in deprived third-world communities (Chávez and Martínez, 1982).

The extent to which PEM affects intellectual potential has been explored by studying the effect of protein-energy supplementation on behavioral development. In spite of different study designs that focused on prenatal supplementation (Rush, Stein, et al., 1980), on postnatal supplementation (Grantham-McGregor, Meeks Gardner, et al., 1990; Husaini, Karyadi, et al., 1991), or in both (Waber, Vuori-Christiansen, et al., 1981; Chávez and Martínez, 1982), results from these studies are consistent in showing that a significant proportion of the variability in mental and motor developmental scales during the first two years of life may be accounted for by nutritional supplementation.

The extent to which the differences in intellectual performance found at early ages in children affected by PEM carries on to later stages in life has been addressed by Pollitt et al. in a long-term follow-up study of Guatemalan children, who received supplements during the prenatal period and the first 2 years of life and were later followed up between the ages of 13 and 19 years old (Pollitt, Gorman, et al., 1995). This study found that children who had received a protein-energy supplement had significantly higher scores on tests of knowledge, numeracy, reading, and vocabulary, as well as a faster reaction time in information-processing tasks compared with children who had received only an energy supplement. This effect was particularly strong for protein-energy supplemented children at the lowest end of the socioeconomic distribution, an interesting finding when compared to only energy supplemented children, in whom the higher cognition test scores varied as a positive function of socioeconomic status, as expected. The authors interpretation is that the protein-energy supplement acted as a social equalizer in relation to the differences in performance usually found in populations as a function of differences in socioeconomic status.

Another long-term supplementation study was carried out in a Mexican village, where women received nutritional supplements during pregnancy and their offspring continued to receive micronutrient supplements from 12 weeks until 10 years of age. Compared to a control group (mothers and children from the same village,

recruited two years before supplementation began), children who received supplements showed significantly better IQs, school performance, and behavior (Chávez, Martínez, et al., 1995).

The studies of the effects of iron deficiency on intellectual and motor abilities were addressed specifically during the 1980s and 1990s. Several well-designed intervention-control studies have shown that, before treatment, average mental scores on the Bayley Scales of Infant Development of infants with anemia were 6 to 14 points lower than the scores of non-anemic controls (Lozoff, Brittenham, et al., 1982; Grindulis, Scott, et al., 1986; Lozoff, Brittenham, et al., 1988; Walter, De Andraca, et al., 1989), and average motor development scores were 9 to 11 points lower, differences of statistical and clinical significance. No significant improvement on the test scores of initially iron-deficient children were noted following iron supplements for two to three months (Aukett, Parks, et al., 1986; Lozoff, Brittenham, et al., 1988; Walter, De Andraca, et al., 1989). Fewer studies have addressed whether these deficits prevail in later ages. In a long-term follow-up study of Costa Rican children at age 5 years whose iron status had been documented and consequently treated in infancy under careful supervision, Lozoff et al. found that at five years of age, all children had excellent iron status. However, those children who had been severely iron deficient during infancy (hemoglobin  $\geq 100$  g per liter) showed lower mental and motor functioning scores at school entry than did the rest of the children, even after controlling for background factors that were potential confounders (Lozoff, Jimenez, et al., 1991). Further, even anemic children with hemoglobin levels  $> 100$  g per liter before and after treatment also had poorer outcomes at five years of age, compared to non-anemic children. Strong as this evidence may be, it is relevant to point out that, to date, there is no definite proof that iron deficiency is the cause of children's lower test scores. For obvious ethical reasons, the gold standard of experimental designs, the double-blind placebo-control study, has not been carried out.

Protein-energy malnutrition also may affect children's performance on cognitive tests by other, indirect mechanisms (often conceptualized as confounding variables in studies that attempt to establish links between PEM and impaired cognition). These include social and economical disadvantages (Johnston, Low, et al., 1987), differences in parental education (LeVine, LeVine, et al., 1991), years of schooling (Ceci, 1991), inadequate attention or affection from caregivers (Engle and Ricciuti, 1995), and other environmental factors, which may include peer interaction, parental presence in the home, etc. (Engle and Lhotska, 1999).

Recent research has addressed the role of breast-feeding (the gold-standard of good nutrition during the first months of life) on cognitive development, adjusting for the aforementioned variables. The results of a meta-analysis that included 11 studies that controlled for  $\geq 5$

covariates on the effect of breast-feeding on cognitive function, a statistically significant increment in cognitive function of 3.16 points was seen in breast-fed infants, consistent through all the studies, at 6 to 23 months of age. This study found a greater benefit of breast-feeding for cognitive development of premature babies (an adjusted benefit of 5.18 points), and a larger benefit in relation to duration of breast-feeding (an increase of the weighted mean benefit of 1.68 points with 8–11 weeks of breast-feeding to 2.91 points with  $\geq 28$  weeks) (Anderson, Johnstone, et al., 1999).

### Concluding Remarks

Over the years, much has been learned about protein-energy malnutrition, its causes, and its effects. Without pretending that all is known, available knowledge can alleviate this burden on human development and social inequalities. Although the treatment of malnourished children all over the world is a clear imperative, the key to solving the problem is to focus on prevention. Preventive actions should be interdisciplinary. These actions should encompass a broad focus on education, particularly directed to women; they should include actions to improve sanitary conditions, schooling opportunities, employment, agricultural produce, and access to diverse food sources, particularly those rich in micronutrients. All sectors of society, including government and non-government organizations, should work together toward a common end. The opportunities to make a substantial improvement in the nutritional status of children all over the world are here, as never before in history. We have studied the causes of malnutrition, its mechanisms, and its consequences. It is now time to study the impact of specific interventions tailored to solve persistent problems.

**MAMMALS.** Mammals—warm-blooded, milk-producing animals—have provided meat protein, milk protein, collagen, hides for leather and shelter, and bones and sinew for various tools since humans began to hunt. Mammals also have provided the power for transportation (still called horsepower) and for heavy lifting or pulling. They have often been regarded as companion animals. Indeed, the existence and progress of humanity have depended heavily on mammals. As human societies became more complex and some took up the settled practices of farming and animal husbandry, certain mammalian species were selected to provide sustainable supplies of meat protein. Bovine (cattle), porcine (swine), ovine (sheep), and caprine (goat) species became valued livestock. Domestic animals, whether raised for food, work, or companionship, were selectively bred by controlling the animals' breeding and food supply to ensure desired traits in the next generation.

### Types of Mammals

The three main classes of mammals, based on food preference, are herbivores, omnivores, and carnivores. Herbivores are strict plant eaters (sheep, goats); omnivores are opportunistic meat and plant eaters (humans, pigs); carnivores are almost exclusively meat eaters (wolves, cats). Mammals, thus, are both prey and predator in any food chain, depending on their size and aggressive behavior.

**Herbivores.** Plant-eating mammals provide most of the world's protein. Virtually every culture around the world tends one of the grazing (herbivorous) species of mammals as a protein source. Dairy cattle, water buffalo, sheep

and goats, camels, yaks, reindeer, and llamas and alpacas all provide dairy products such as yogurt, cheese, butter, and milk in various societies.

Cattle originated in northern Europe and were domesticated by the northern Germanic and Celtic tribes in approximately 4000 B.C.E. Romans then brought them into southern Europe in the first century B.C.E. From the upper reaches of the Nile to the plains of southern and eastern Africa, cattle herding was common. Cattle became the basis of wealth for warrior-dominated societies in southern Africa. During the Middle Ages in Europe, cattle represented real wealth as milk providers and as work animals, not as meat animals. Cattle were slaughtered only when they could no longer work. Beef was not widely eaten, as cattle and oxen (castrated dairy bulls) had tough, dry flesh.

Water buffalo, valuable for hauling, transportation, and other work, were also used for milk, and buffalo milk mozzarella is still enjoyed as a table cheese in Italy.

Sheep and goats, small ruminants, are kept for their fleece, hides, meat, and milk. Both are docile and socially inclined mammals, and were herded beginning in 8000 B.C.E. in southwest Asia. Camel, yak, and reindeer are herding animals that provide meat, milk, and hides for the nomadic tribes of Asia and the Arctic Circle, respectively. Reindeer herding developed in the northern latitudes even before herds were kept on the Eurasian steppes. Camel herding became common in Arabia and the Sudan of Africa, and camels were critical to the maintenance of trade routes that crossed the great deserts of Africa and Asia. The yak, a large, long-haired ox with a bushy tail, is native to the Tibetan plateau. It provides dairy products and is used for transport. Llamas and alpacas have provided the peoples of Peru and Bolivia with hides, fleece, meat, and milk since at least 3500 B.C.E.

The American bison, the largest land mammal of North America, is believed to have migrated from the steppes of Central Asia into what is now Alaska by crossing the narrow strip of land (Beringia) that existed during the last Ice Age. Native Americans revered bison for the wealth it provided in clothing, food, and tools made from sinew and bone.

Deer, along with their cousins—elk, moose, and caribou—are antlered, hoofed ruminants. These grazing animals supplied food and clothing to both Native Americans and, later, the European invaders of the North American continent. Antelope are the surviving members of an ancient family of grazing animals native to North America. Lewis and Clark, on their long exploratory trip across the continental United States, found large herds of antelope on the Great Plains. Gazelles and other wild grazing animals of Central Africa and Central Asia are hunted by native peoples for their meat.

Many species of small game have provided meat and fur when large game was not available. Wild hares and some rabbits, both native to Europe and the Americas,

Traditional bowl made of grass fibers for milking camels. Oman, twentieth century. The handle and exterior covering are goat hide. ROUGHWOOD COLLECTION. PHOTO CHEW & COMPANY.

are hunted, while other breeds of rabbit are reared specifically for consumption. Muskrats, sometimes called “marsh rabbits,” and squirrels are rodents found throughout North America; both have supplemented the human diet. Squirrels are still hunted today in many parts of the United States and are usually served in a stew. Guinea pigs are popular in many Peruvian dishes, especially in the Andes, where these herbivorous rodents (much larger than the guinea pigs kept as pets or laboratory animals) are raised in many households, like rabbits elsewhere. Rats and mice are rarely eaten, though both have provided meat for people in times of famine.

The beauty of its fur led to the beaver’s being overhunted by British, French, and Russian trappers in the northern territories of the North American continent in the sixteenth and seventeenth centuries. Beaver pelts were in great demand in Europe, especially for men’s top hats. The fatty tail of the beaver was also prized for food. In the Middle Ages, the tail was declared “fish” by the Catholic Church, since the animal lived in water, making it acceptable as a meal on meatless days. Because its meat is very strong, only farm-raised beavers are recommended for cooking.

Kangaroos and opossums, both marsupials, are not consumed widely, though in Australia a cottage industry has developed around the production of kangaroo meat. Opossums, though not farm-raised, are hunted in the southern states of the United States for their meat.

**Omnivores.** Pigs are descended from a distant ancestor in southern Asia. Domesticated pigs brought to North America by the Spanish occasionally escaped captivity and multiplied, increasing the populations of wild pigs in the southeastern United States. Other breeds subsequently brought to the United States also occasionally

escaped and bred with feral pigs, further mongrelizing the pig population.

Peccaries, known also as javelinas, North America’s native wild pig, are not related to domesticated pigs and wild boars. Peccaries belong to a separate genus indigenous only to North America. They favor a warm climate and are hunted in New Mexico, Arizona, and Texas.

Raccoons range widely throughout the United States. Although valued primarily for their fur, their meat was commonly eaten during colonial times, and raccoons are still hunted for their fur and meat in the southern states of the United States.

Archeological evidence suggests that bear meat was consumed by native peoples in North America following ritual hunts. Bear meat was prized by European colonists and Native Americans, mainly for its fat for cooking. Though not a widely popular meat, bear are culled from game reserves and the meat is sometimes available frozen.

**Carnivores.** The small Asiatic wolf, a social animal and meat eater—the ancestor of our canine companions—was reportedly domesticated as early as 11,000 B.C.E., probably because it was more useful for herding and hunting than as a source of food. This is not to say that the dog was not a source of meat. Dog meat has been eaten and enjoyed in Asian cultures, and is still commonly consumed in both China and Korea.

### Domestication

Although the history of domestication of mammals by humans is not recorded, archeological evidence suggests that it occurred on all continents between 7000 and 10,000 B.C.E. Each human group chose local migrating herbivores for domestication on the basis of their availability and docility. The first mammals to live with people were likely wolves and small ruminants such as sheep and goats. By the end of the second millennium B.C.E., civilizations based on livestock domestication and agriculture had emerged in Asia, Europe, and Africa. Small grazing animals like deer and sheep, which could provide meat, milk, and fiber, were probably herded by humans as they roamed the broad landscapes of western Asia. No evidence exists that early humans domesticated the numerous grazing animals of Africa.

**Goats and sheep.** Besides being docile and adaptable, goats and sheep breed successfully in the company of humans, and in time each generation gradually lost more of its feral nature. It is widely believed that the goat was the first herding animal to be domesticated, due to its gregarious nature. As the Romans moved north through Europe during the first century B.C.E., sheep and goats accompanied them, becoming sources for the wool industry, and mutton became a readily available meat. Sheep store fat well and so are efficient animals to maintain.

Goats are browsers, able to digest not only grasses but also woody shrubs and less desirable plants. Goats

are even more adaptive and less choosy about their diet than sheep and can graze in arid climates. Goats continue to be prized for their milk and the resulting fermented dairy products. Goat meat, particularly the tender and milder flavor of kid, was enjoyed throughout the Mediterranean and the Asian continent and is also eaten in some regions of the Americas.

**Cattle.** The ancestor of today's domestic cattle, the aurochs (*Bos primigenius*), is extinct. Members of the bovine genus inhabited most of the world's continents and were introduced into the Western Hemisphere during the European conquests of the late fifteenth and early sixteenth centuries.

Asian cattle, also known as humped back cattle (*Bos indicus*), have provided meat and motive power on the Asian subcontinent. Religious and cultural beliefs in India prevent cattle from being consumed as food, although the milk can be used. In Africa, cattle are probably descended from European and Indian breeds introduced by traders, probably in the first millennium B.C.E.

Veal, meat from castrated young dairy bulls, was a choice dish even in ancient times. Just-weaned calves produce veal, which still brings a handsome price, more per pound than beef. Veal is a light-colored meat because the animals are fed milk or milk-replacer diets and are never permitted to graze.

The distinction between beef and dairy cattle breeds began in eighteenth-century Europe. Breeds that were best for beef and those best for milk production were identified and cultivated. Among the dairy-consuming peoples of northern Europe, the dairy breeds of cattle were selected for the high butterfat content of their milk.

It is generally believed that cattle first came to the North American continent with the Spanish. Columbus carried cattle to Santo Domingo in 1493, and in 1519 Cortés brought long-horned Andalusian cattle to Mexico. In the early seventeenth century, Spanish missionaries were raising cattle throughout the southwest United States.

**Pigs.** The ancestors of domestic swine were dispersed throughout Europe, Asia, and North Africa. The nomadic lifestyle of early peoples precluded their domestication. They were probably first encountered as pillagers of crops and therefore hunted, but young pigs might have been taken into early settlements and raised for meat. The omnivorous habits of the pig meant that it could thrive on the scraps from humans combined with its own rooting and foraging.

Pigs have evolved gradually over a period of ten million years with a few minor variations. Early pigs were taller than six feet, with an elongated wedge-shaped head, lacking a modern pig's snout, and a body shape similar to that of the European boar. This ancestor of the pig ranged from Europe to Asia and became the ancestor of the European wild boar.

Columbus is credited with bringing the pig to the Americas in 1493. These hogs ran wild throughout the Spanish West Indies, and were later joined by a load of pigs that arrived in Mexico with Cortés in 1521. On his trek west to the Mississippi Delta in 1539, Hernando de Soto brought pigs from the West Indies to Florida.

**Dogs.** Evidence suggests that early canine-human interactions may have occurred over the kills of larger wild herbivores, leading dogs and humans to be wary competitors at first but ultimately to become allies. Bones of dogs are common in campsites of the late Stone Age from around 7000 to 6000 B.C.E. The Asian wolf was probably the first wild animal domesticated by humans, and it is believed to be the ancestor of all domestic dogs. Until the eighteenth or nineteenth centuries, most of the breeds of dog were described by their purpose (wolfhound, sheepdog), and it was not until the nineteenth century that many breeds were developed.

**Horses.** The earliest fossil examples, Eohippus, are found in northwestern North America. This wild ancestor of the horse was not much larger than a cat and had four toes on its forefeet and three on its hind feet. It was probably very widely distributed across the globe. Around 4000 B.C.E. the horse was domesticated in eastern Europe, and played a significant role in transportation, draft power, and warfare. Mounted soldiers were important military weapons until the twentieth century. Modern horses were reintroduced to the Americas by the Spanish conquistadors and were quickly adopted by native peoples for transport.

**Game mammals and hunting.** Those mammals not domesticated were hunted. Hunting animals for food or sport, or to rid a locale of animals that are seen as pests, is a human activity that spans the centuries and the globe. As early as the Late Paleolithic period, successful hunts required methods to preserve meat after slaughter. Meat was dried, smoked, or frozen in pits dug in the earth, or carcasses were weighted down with stones and sunk in cold lakes that froze during the winter. Meat stored was eaten dry, boiled, or grilled.

Hunting still provides some animal protein for the human diet; amounts vary depending upon the culture and region. In developed countries, hunting is largely a sport, while in less developed countries it remains, with fishing, an important source of dietary protein.

## Nutrition

**Meat.** Meat is a popular high-quality protein food that satisfies the appetite and taste of people around the world. With the exception of organ meats, which tend to have concentrated nutrients, all of the cuts of meat from an animal are equally nutritious, providing roughly equivalent amounts of protein, minerals, and vitamins. Nutrition experts recognize meat as a food that also contributes varying amounts of fat to the diet. Meat supplies com-

plete protein (all essential amino acids), essential minerals such as iron and phosphorus, significant B-complex vitamins (for example, thiamin), and trace minerals such as zinc. The protein of meat is comparable to that of fish, poultry, eggs, and milk.

The consumption of organ meats is sometimes encouraged because of the extremely rich vitamin and mineral content contained in edible glands and organs, including the liver, heart, kidneys, brain, sweetbread (thymus gland), tongue, tripe (stomach), and testicles, as well as the lungs and spleen in some cultures.

**Dairy.** Dishes prepared with milk or cheese are sometimes called “meat alternates” because of the similarity of the nutrient profiles, particularly when it comes to complete protein. The most significant milk products are:

- **Yogurt:** A fermented milk product made from whole, low-fat, or skim milk, providing all the food value of the milk from which it was made.
- **Cultured cream:** A product similar to yogurt but made with cream and so higher in butterfat. Sour cream is used widely in eastern European cooking; crème fraîche is more popular in France.
- **Butter:** A concentrated milk fat that provides fat in the diet and fat-soluble vitamin A.
- **Cheese:** A concentrated form of milk, fermented and often aged, that loses some of its protein in the cheese-making process but remains a high-protein food.

### Mammals and Human Societies

Mammals have long played an important role in human mythology, religion, and social customs. As an act of reverence, humans have sacrificed animals, drunk their blood, and eaten their flesh. There are also taboos against certain relationships between humans and some animals, from the kosher prohibitions on eating pork and certain cuts of other animals to sexual taboos concerning congress between man and beast. Animals have been believed to be the habitat of both evil spirits and the souls of deceased human beings. Superstitions abound about animals, from bad luck brought by a black cat crossing one's path to good luck brought by carrying a rabbit's foot.

### *Culture, religion, symbolism, tradition, and taboos.*

Animal worship figures in many cultures and religions, including the cow among Hindus and the cat in ancient Egypt, and involves the role of reincarnation in some Asian religions. In many cultures, the spirits of important food animals were appeased to ensure their continued fertility, or ceremonies were performed to propitiate predators that threatened human survival. Stone Age art, cave drawings dating from 20,000 to 40,000 B.C.E., shows the animals and activities most important to the peoples of those cultures. The archeological evidence strongly suggests that these early people hunted and killed wild animals. Anthropologists believe the caves in which these

drawings are found were not dwellings but served a religious or ritual function because food animals and hunting scenes predominate.

The earliest records of meat consumption indicate that animals were ritually slaughtered and the meat distributed to members of the community on the basis of an individual's place in the social hierarchy. Such practices required settled groups engaged in crop and pasture production. With farming and the formation of population clusters came the division of labor necessary to support specific food practices—grain milling, baking, meat processing, leather tanning, and so on. In some societies, meat processing emerged as part of sacrificial offerings to the deities for atonement, appeasement, supplication, or thanksgiving.

**Meat eating and religious practices.** In ancient times, sacrifices to the gods and goddesses often consisted of roasted sheep, goats, and lambs. Homer, Virgil, and the authors of the Old Testament all give accounts of roasted meat being offered to please the gods or the Lord. The biblical Book of Leviticus stipulates that the sacrificial animal be perfect, without any physical flaws; thus, a castrated animal was forbidden as a sacrifice.

The story of Adam and Eve in the Book of Genesis suggests that humans were created essentially vegetarian. Meat eating followed Eve's transgression. Under the laws of Kashrut, which govern kosher practices, Jews are forbidden to eat pork and shellfish (“tref”). In addition, certain parts of an animal, such as the hindquarters (unless butchered in a special fashion) as well as some organ meats, are forbidden. Another dietary restriction is that meat and milk may not be eaten together. These limits have resulted in fewer choices when it comes to meat for Jews than for others.

Muslims also do not eat pork, and, like Jews, they slaughter their meat according to religious guidelines. Such meat is called *halal*, or lawful. The month-long fast of Ramadan, while strict, is more of a joyful occasion than the Christian Lent, a forty-day period of abstinence and penitence.

The Roman Catholic Church established many restrictions on eating meat on certain days during the year, particularly during Lent and on specified fast days. Until the reforms of Vatican II (1962), meat eating was traditionally forbidden on Fridays. For generations, fish on Fridays was the rule in Roman Catholic communities. Meat, broth, and fat from warm-blooded animals were forbidden, while meat from waterfowl and from cold-water fish was considered acceptable.

Given the Church calendar—abstaining from meat on Fridays, on the eve of certain feast days, and on other days as well—meat eating was forbidden almost every other day: 180 days a year. The Orthodox Church was even stricter. This refusal to eat meat and fat (including butter in some times and places) had an ascetic aspect as well as a penitential one in its denial of human desire. In

## ANIMAL RIGHTS

The animal rights movement is a loose-knit coalition of groups who oppose abusing, mutilating, or killing animals to serve human purposes, including inhumane “farming” methods to raise animals for high-status luxury items like fur and leather. Most visible in North America and Europe, the movement includes benign meat eaters and farmers who want to ensure that livestock are treated humanely to vegetarians to activists who smear blood on fur coats and urge supermarkets to remove their lobster tanks. The politically and ideologically motivated efforts have had an impact on mainstream economics, although those with a financial interest dismiss their efforts as romantic or as malicious and dangerous, especially if they still believe that humans are superior to other animals and, therefore, that they have the “right” to do whatever they wish to them in the name of some “grander” (human) purpose. Research has demonstrated that the humane treatment of animals actually improves production and meat quality. Some of the results of that research have been incorporated into animal raising practices. In addition, some major food companies have adopted policies for their meat suppliers that stipulate humane handling practices, and some retail food packages—for example, chicken sausage—bear labels declaring such policies. As people grasp the “radical” idea that animals feel pain and, like humans, have the right not to suffer, whatever the rationale, the animal rights movement grows.

production has caused numerous environmental problems that endanger humans as well as the animals bred for food.

***The risks and costs of high-intensity animal production.*** Since World War II, agricultural production has striven to produce more from less without, some critics say, thought of the consequences. With high-intensity animal production, because animals are kept in close quarters they are more susceptible to the various diseases and parasites afflicting livestock. To counter disease and parasitism, scientists developed inexpensive pharmaceuticals to protect and treat animals. Surprisingly, many of these drugs actually improved livestock feed conversion performance faster than breeding and breed selection. As a consequence, livestock producers adopted these products widely, and meat production operations grew and consolidated in rural areas near feed grain sources.

India cattle are not consumed because of the religious proscriptions of the Hindu faith. Since pigs, goats, and sheep are raised for meat and milk, however, India is not entirely vegetarian. Butter from the milk of sacred Indian cows was made for religious ceremonies, and ghee, a kind of clarified butter, is used for cooking.

***Meat eating and vegetarianism.*** Meat, whether from mammals, poultry, or fish, provides a concentrated, easily digestible source of protein and fat. Ruminants in particular are able to convert herbaceous material into muscle more efficiently than monogastric animals, such as pigs or poultry, and are therefore better suited as sources of meat protein.

A vegetarian diet—eschewing meat or any animal food products—is undertaken by individuals for many reasons: health reasons and concern for the environment, ecology, and world hunger issues. Vegetarians often also cite economic reasons and ethical considerations as reasons. For some, religious beliefs dictate following a diet that avoids animal products. In India, for example, many are vegetarians because they find the taking of life abhorrent; in addition, many believe in reincarnation and fear that a living soul could be inhabiting a living creature.

Significant scientific data suggest links between a vegetarian diet and reduced risk of developing several chronic degenerative diseases and conditions, including heart disease, high blood pressure, diabetes, obesity, and some types of cancer.

The eating patterns of vegetarians vary considerably. The lacto-ovo-vegetarian diet is based on grains, vegetables, fruits, legumes, seeds, nuts, dairy products, and eggs, and excludes meat, fish, and fowl. The vegan, or total vegetarian, eating pattern is similar with the additional exclusion of eggs, dairy, and other animal products, even honey. Even within these patterns, considerable variation exists in the extent to which animal products are avoided.

Human beings, however, have been omnivorous since before recorded history. It seems unlikely that they will turn en masse to vegetarianism. In fact, arguments from the 1968 Rome conferences of the Food and Agriculture Organization of the United Nations suggest that humans could not abandon the consumption of meat in favor of a solely vegetarian diet. There was not, nor is there now, sufficient arable land to produce adequate protein or calories for the world's population.

### Global Issues

While some of the problems discussed here primarily reflect events and situations in Europe and the United States, their repercussions will almost certainly have global consequences as impoverished regions of the world struggle to provide a nutritious diet for their increasing populations. What began as animal husbandry in prehistory threatens worldwide disaster. As the human population has increased beyond the capacity of the planet to feed its numbers, the practice of high-intensity animal

Feedlots and large poultry operations, however, though extraordinarily efficient, are smelly and environmentally risky as well. Also, starting in the early 1970s, mounting public concern about the residues of pharmaceutical products in meat used for human consumption entered the debate about the wisdom of intensive livestock production. The food supply seemed to be contaminated with unnecessary, and perhaps toxic, chemical substances, and the methods of raising animals that required their use became targets of public protests. One result of these concerns has been the increase in sustainable livestock production, sometimes called “natural” or “organic” production. In natural production the animals are raised without performance-enhancing chemicals or feed additives. Livestock living in herds are as susceptible to disease as those raised in close quarters, and the effects of disease are devastating to herds. However, ranchers claim that it is more expensive to raise pigs or cattle without the aid of drugs or additives and so justify the higher prices charged for such meat.

Organic livestock production is stricter still, involving the feeding of grains and oil seeds produced under National Organic Standards. As adopted by the U.S. Department of Agriculture (USDA), the National Organic Standards specify that livestock and poultry may not be treated with antibiotics or any medicine and must be fed grains and rations that derive from organic crop production.

Intensive livestock production systems are based on concentrating large numbers of animals (housed or not) on small parcels of land and feeding them high-energy diets that guarantee the fastest weight gain in the least time. While feed efficiency (pounds of gain per pounds of feed) is important to the owners of such systems, intensified livestock production also results in large-scale animal waste. The concentration of live animals in a total confinement unit rivals a small city in terms of the annual waste output. Cities of such size are required by law to maintain tertiary water treatment facilities to handle their wastewater outfall. No such provision has yet forced pig or cattle feeders to treat their production wastes in a similar manner.

Among mammals, pigs represent the biggest waste threat to the environment because of the very large confinement units used to raise them. The most efficient pig will convert two pounds of feed into one pound of additional body mass, not all of which is edible protein. In order to acquire that pound, the animal produces one pound of feces and urine. Cattle are even less efficient, converting twelve to eighteen pounds of feed to one pound of body weight during the last weeks of feeding. This waste presents a considerable disposal problem.

With the animals living in such limited space, the waste must be stored for later treatment or use. In the past, this meant applying the manure as fertilizer to agricultural land, but this method of handling manure is no longer sound. Lagoons that hold animal waste often leak

or break, with disastrous consequences for local streams and lakes. The open pools of raw waste also fill the surrounding countryside with a prevailing stench. The recent history of such environmental disasters and resulting legal battles is a complex story about shifting the costs of production to others, including future generations. Moreover, the available solutions cost money, so are unacceptable to those watching the bottom line. Steel holding tanks or glass-lined tanks, for example, clearly better containment choices, are prohibitively expensive, usually more than the average pork or beef production operation can, or is willing to, pay. With the infusion of new capital into pork production in the late 1980s, more attention was given to waste management, but the disposal problem has not yet been solved.

Intensive livestock production poses other risks to the environment and human health, for example, pollution of surface and ground water by animal waste. Such spills contaminate water, cause loss of property values for residential land, and harm recreational areas. The frequent and periodic contamination of ground and surface water from manure spills has become a familiar headline, reminding the public that profit-driven production methods endanger their health and the welfare of future generations.

With the appearance in the 1990s of bovine spongiform encephalopathy (BSE; more familiar to the public as “mad cow disease”) in England and France, and the deaths caused by its spread to humans who ate meat from diseased cows, vigilance with respect to safe meat production became even more critical. In spite of research demonstrating that the disease had been spread in herds that had eaten feed that contained meat products, some feed suppliers in the United States were found continuing the practice in 2001, and, without enough USDA inspectors to monitor meat production from start to finish, the public cannot be sure that the meat they eat does not come from cows infected with BSE.

Facing continual pressure from environmentalists, real estate developers, and non-farm landowners, livestock producers struggle with presenting a responsible image. This reality applies both to producers managing large, intensified operations and to those who pasture their livestock. In terms of the stocking capacity of open land, whether for cattle, pigs, or small ruminants, it is now being argued that small ruminants (sheep and goats) can provide as much meat per acre as cattle or pigs without the subsequent environmental risks. Raising dual-purpose sheep or goats (those that provide both food and fiber) can be a more efficient use of limited land resources than the typical practices of cattle ranching.

This issue will become more pressing in the future as residential suburbs push into traditionally rural areas. The resolution will need to be political because of the constituencies involved. Technological advances have made the cost of farming too expensive for family farmers. As they are forced to sell their land to the giants of

agribusiness or go into bankruptcy, farmers are becoming a smaller and smaller percentage of the population, and their real voice in legislatures will continue to diminish. City dwellers will demand that a fairer burden of the cost of farming be placed on those who profit from it than has been the practice since the New Deal under Franklin D. Roosevelt's administration in 1932–1940.

Another aspect of the urban-rural confrontation involves the cropping practices needed to support the intensified meat-production industry. Of the more than 70 million acres of corn grown annually in the United States, more than 65 percent is used for animal feed, and the price of corn drives all other commodity prices. Federal farm policies during the twentieth century resulted in overproduction of corn and soy relative to world market demands, depressed world prices, and significant loss of farm income. Add to this the loss of agricultural diversity and soil productivity caused by producing the same crop or the same rotation of crops on the same land year in and year out. Such farming practices had forced farmers to use more and more chemical pesticides and fertilizers in order to achieve uniform yields. Biotech crops may be a solution, because they permit more intensified cultivation and higher yields. However, controversy remains within the scientific community about the sustainability of high yields from biotech seed crops. This concern is added to the ongoing problems of groundwater contaminated with fertilizer runoff and pesticides.

**Bioengineering.** Unlike plant biotechnology, which has quickly introduced numerous varieties of common plants genetically reengineered to include certain traits, such as resistance to common pests for corn, animal biotechnology has had little success in changing the basic properties of livestock or poultry. A few applications of genetic manipulation may eventually prove useful in producing meat protein for human consumption. Of these, cloning is the most obvious and most likely to succeed, if public opposition fails to halt such research. Cloning livestock requires the nuclear transfer from an animal with the most desired traits (for example, efficient feed conversion, muscling, and tenderness) to eggs from the same species. One application would be the cloning of highly desirable boar and sow lines to be used in creating market pigs with specific, repeatable characteristics.

The technology for cloning livestock at this time is prohibitively expensive compared to conventional breeding or artificial insemination. For this reason, cloning is not expected to make a significant contribution to meat production for years. Such genetic manipulation also arouses considerable controversy in public and scientific discourse regarding the ultimate safety of food derived from such genetically modified organisms.

As populations continue to expand and the food crisis intensifies, the twenty-first century will witness societies worldwide struggling with the multitude of social,

environmental, economic, and health issues that surround the production of livestock.

Robin Kline

**MAMMALS, SEA.** Sea mammals provide meat and fat in the diet of cold-climate-dwelling hunters living primarily in the Northern, but also the Southern, Hemisphere. The skins and fur from sea mammals provide clothing and shelter, while the bones and ivory tusks are carved for tools, talismans, and objects to be sold as art. The fat may be processed for oil to eat or to be used for heat and light. Offal, fat, and less desirable meat products are often fed to dogs.

The most common sea mammals in the human diet are the many species of *Phocidae*, seals. Other sea mammals commonly eaten include walrus, *Odobenus rosmarus*; whales, *Cetacea*; polar bears, *Ursus maritimus*; the bearded seal, *Ergnathus barbatus*; porpoises, *Phocena*; narwhals, *Monodon nanuk*; sea lions, *Eumetapias jubata* and *Otaria jubata*; and fur seals, *Callorhinus ursinus alsacensis* and *Arctocephalus australis*. Seals, walrus, polar bears, bearded seals, sea lions, fur seals, and porpoise feed on fish, but seals also eat krill. The most commonly hunted and consumed whale is the baleen whale, which filter-feeds on plankton. Polar bears, considered by Arctic native people to be a sea mammal, eat seal, fish, and other land mammals, but are known to be omnivorous. The livers of the meat-eating sea mammals are never eaten.

Arctic coastal-dwelling Canadian Inuit, Alaskan Aleut and Yu'pik, and Siberian Eskimos are best known for hunting seals. Northern Alaskan Inuit, for example, who live on the North Slope and Point Hope, are famous for hunting whales. All Sikumiut (sea-ice-dwelling) peoples share histories of hunting all sea mammals. North Baffin Inuit, for example, begin the spring with hunting seals through breathing holes; infant seals are stomped in their mother's dens in late spring; juvenile ring seals, prized for their silver coats and tender meat, are hunted in late spring, while the adults are hunted as they bask near open water leads. Dangerous trips are taken to the pack ice to hunt migrating narwhals, and summer brings open-water seal hunting from cargo canoes. Freeze-up in the fall brings the return of breathing-hole seal hunting, which extends through the winter months. Polar bear season begins in the late fall and continues through the winter months. Summer bear hunting is not possible due to Canadian conservation laws. The large baleen whale species in the eastern Arctic were overhunted by European whalers in the nineteenth and early twentieth centuries. Since then, eastern Arctic Inuit rarely have hunted whales.

A complex set of skills is required to hunt sea mammals. Cooperative hunting requires an adaptive social organization specific to each sea mammal species. Cultural rules and rituals ensure that the values of sharing, patience, cooperation, stoicism, and emotional containment prevail among Arctic social groups. The social organization used by peoples in northern Alaska for hunting large whales surpasses the complexity of all Arctic groups, but does not need to be maintained intensely for subsistence hunting of other sea mammals. Lone hunters can hunt

polar bears and seals, but it is difficult. Breathing-hole hunting is better done with at least two hunters and/or families, and polar bears are less dangerous to hunt with a group. Bear are pursued with a .306 rifle, but have been harpooned or shot with bow and arrow. Walrus, because they are dangerous, are hunted by groups armed with harpoons or large-caliber rifles. In general, the larger or more dangerous the sea mammal, the greater the need for a complex social organization when hunting.

In the Subarctic, seacoast-dwelling native people depend on sea mammals, with those closest to the Arctic being most dependent on them for food, clothing, and shelter. The Tlingit, who live in southeastern Alaska and northwestern coastal Canada, follow an annual cycle of hunting that includes summer sealing camps when harbor seals, fur seals, and sea lions are hunted. There are two sea otter hunts in the fall, another sea otter hunt in the early spring, and late spring concludes with both seal and sea otter hunting. The Tlingit use bows and arrows to hunt small sea mammals and harpoons for open sea hunting, while the Quinault, who live in the state of Washington, use bows and arrows to hunt sea lions and hair seals, which they dry and boil, during the summer. Both of these societies have developed social structures that make cooperative hunting and food sharing possible.

The Eastern Woodland seacoast-dwelling Micmac occasionally hunt seals, but focus primarily on land mammals. At the other end of the earth, the Selk'nam of Tierra del Fuego feast on the flesh of beached whales and seals, but do not actively hunt them because they lack the kind of social organization necessary for actively hunting sea mammals.

The meat, skin, fat, bones, and specific organs of sea mammals are consumed both cooked and raw. Uncooked seal, bearded seal, walrus, whale, and polar bear are relished by Inuit from Siberia across the circumpolar region to Greenland. Inuit also prepare the flesh of sea mammals by boiling, frying fresh meat slices, freezing, aging it in caches, freeze-drying, and cooking it over a heather fire. Although the Inuit once ate polar bear and walrus meat raw, they no longer do because of the risk of Arctic trichinosis, which can survive freezing conditions and infect human hosts. Other meats are safe to eat raw due to the low temperatures and the lack of food-borne pathogens when meat is traditionally processed. The introduction and use of airtight plastic bags for meat storage in the second half of the twentieth century caused deaths from botulism. For this reason, traditional food storage and handling methods are recommended for people who live on the ice.

Subarctic populations cook meat in stews and soups or bake, roast, or fry it. Mixed meat and vegetable dishes are also prepared. Meat strips are dried or smoked and stored. Sea mammal meat was not as important among the Subarctic populations as in the Arctic because of the abundance of other food resources.

Seal and whale oil are significant in the diet of both Arctic and Subarctic hunters. The oil, which provides an excellent source of energy during periods of hunger, such as at break-up and freeze-up, is rendered by pounding fat on a hard surface. Plants and raw or dried fish, meat, or skin are dipped in either fresh or aged oil. Both Arctic and Subarctic peoples will whip seal or whale blubber and add bits of meat and/or plants for flavor.

Seal blood is consumed by Inuit and considered a powerful tonic that improves their mental and physical health. Strong beliefs are held among Inuit concerning the need to eat traditional foods, especially seal, to maintain the health of individuals as well as that of their communities.

The meat of whales, seals, bearded seals, walrus, narwhals, and polar bears is divided and shared according to cultural rules at the end of the hunt among both Arctic and Subarctic groups. Meat and all the edible parts of killed animals is distributed at feasts after large organized hunts. Furs are usually retained as the property of the hunter but can be shared as needed in the community. Families meet at the feast to collect their share but return home to further distribute and consume the food.

Cooperative hunting and food sharing define Arctic and Subarctic hunting populations socially. Sea mammals have an essential role in the diet of all circumpolar and some Subarctic groups. Human exploitation of sea mammals has allowed hunters to flourish in regions under frigid environmental conditions.

**MARDI GRAS.** See *Shrove Tuesday*.

**MARGARINE.** Margarine was invented by Hippolyte Megè-Mouriès in 1869 in response to an order from Napoleon III to produce a cheap and stable substitute for butter. The product had a pearly luster, and Megè-Mouriès named it margarine after the Greek word meaning 'pearl-like'. The process of manufacture entailed churning oleo oil (obtained from beef tallow) at 77 to 86°F (25 to 30°C) with water or milk. The product was flavored with salt. Over time margarine has been used in baked goods, to improve the palatability and quality of butter, to improve heat transfer during frying, and to add to the flavor of foods. Margarines may contain about 80 percent fat (animal or vegetable), milk solids, emulsifying agents, and salt.

The U.S. Food and Drug Administration (FDA) established a standard of identity for margarine. It must contain not less than 80 percent edible fat of animal or vegetable origin; water, milk, or milk products; suitable edible protein, and vitamin A. Optional ingredients include vitamin D, salt or potassium chloride, nutritive carbohydrate sweeteners, emulsifiers, preservatives, colorants, flavorants, acidulants, and alkalizers. Fat-free and low-fat spreads are available commercially. While it is convenient to describe them as margarines, they do not conform to the FDA standard of identity. Early in the

twentieth century the texture of margarine was improved by replacing animal fat with coconut oil. In the 1930s hydrogenated vegetable oils became available, and these became the basic ingredient of margarine. Hydrogenated vegetable fat provided a uniform base for margarine, and control of the extent of hydrogenation gave a series of fats of varying hardness that could be used for specific products.

The hydrogenation process causes migration of the double bonds of vegetable oils and provides both cis and trans double bonds, whereas the double bonds in most vegetable oils are in the cis configuration. A cis double bond is one in which the hydrogen atoms attached to the carbons that form the double bond are on the same side of the carbon chain, and the molecule "bends" at the site of the double bond. In trans double bonds the hydrogen atoms are on opposite sides of the carbon chain, and the molecule has a more linear configuration, similar to that of a saturated fatty acid. Trans double bonds are not unknown in nature, occurring in many plant fats and some animal fats. Where most of the vegetable fats contain eighteen carbon atoms or more, the trans animal fats are generally shorter than eighteen carbon atoms.

Concern regarding the biological effects of trans double bonds was voiced in the 1940s. Studies of effects of trans fats on growth and reproduction in rats show that they have no untoward effects when the diet is replete in essential fatty acids, but when fed as the sole source of fat, they exaggerate symptoms of essential fatty acid deficiency. In this they resemble saturated fatty acids, as they do in many other biological processes.

The effects of trans fats in experimental atherosclerosis were first examined in the 1950s by Gardner McMillan and his colleagues. They found that, while trans fats raised blood cholesterol levels in cholesterol-fed rabbits, their presence in the diet did not lead to more severe atherosclerosis. Studies of rabbits fed cholesterol-free diets, of pigs, and of vervet monkeys have yielded similar results. One six-year study of the effects of partially hydrogenated soybean oil yielded atherosclerosis at a level of severity seen in rabbits fed coconut oil and less than that seen in rabbits fed soybean oil.

In humans the effects of trans fats on cardiovascular disease can only be assessed by effects on risk factors. Early studies yielded variable results of trans fat-rich diets on serum cholesterol. It was observed that the level of hypercholesterolemia varied inversely with the amount of linoleic acid in the diet. Trans fat was not hypercholesterolemic in diets that were also rich in linoleic acid. No differences were found when tissue levels of trans fats in human subjects who had died of cardiovascular disease were compared with that in human controls.

Analysis of human studies in which energy from carbohydrates was replaced by trans-18:1 fat shows that this exchange leads to increases in levels of LDL cholesterol and decreases in levels of HDL cholesterol, which in-

creases the risk of cardiovascular disease. Serum levels of lipoprotein(a), another risk factor, are also increased.

Epidemiological studies of the effects of dietary trans fat on coronary heart disease yield variable results. One study (239 cases and 282 controls) shows a positive association between high intake of trans fat and coronary heart disease (CHD) risk but an inverse association at moderate intake, whereas another study carried out in nine European countries (671 cases and 717 controls) found no association between intake of trans fat and CHD risk. Cohort studies found positive associations between intake and risk only at the highest level of intake. Two studies found the lowest risk at the third quintile of intake. The Seven Countries Study revealed a significant positive association between 18:1 trans fatty acid intake and twenty-five-year CHD mortality rates.

The overall findings concerning intake of trans fat and risk of CHD are not consistent. These disparities are complicated because the data regarding effects of specific trans fatty acids are sparse and differences between populations and interactions with other dietary ingredients are not considered. The trend to consider dietary patterns rather than individual dietary ingredients may help organize the findings. Nevertheless the sum of the experimental data suggests that high intake of fats containing trans fatty acids may pose an increased risk of CHD. The industry response to these findings has been a major effort to produce margarines that are either low in trans-unsaturated fat or devoid of it.

Much is unknown about the balance of dietary fats—trans fat, saturated fat, and polyunsaturated fat and their interactions with other components of the diet. The attitude should be one of prudence, not panic.

**MARINATING AND MARINADES.** Marinades are used to enhance the flavors of grilled meats, seafood, and fruits and vegetables. Seemingly simple concoctions of acids, fats, and aromatics, marinades are used around the world; for example, Jamaican jerk, Indian *tandoor*, and Texas barbecue are marinades that form the basis of particular cuisines.

Simply put, tradition or a creative chef dictates the combination of flavors that compose the marinade, in

which selected meats, seafood, or fruits are macerated for a period of time. This technique allows the marinade to transfer some of its flavors to the outer layers of the food. When the food is grilled, the marinade blend imparts a new flavor to the food being cooked.

For delicate seafood, such as a teriyaki-glazed grilled salmon, marinades baste the outer surfaces with a soy-sweet flavor. The taste of briefly marinated fruits and vegetables (i.e., pineapple briefly soaked in light vegetable oil, rum, and brown sugar) improves greatly.

More practically, marinades tenderize the tougher fibers of inexpensive cuts of meat. Acid causes the denaturation of the long proteins in meat, rendering the meat tender as well.

#### Cooking and Safety Precautions

Any excess marinade must be first boiled or reduced before being used as a side sauce, to completely kill any bacteria associated with the raw meat or seafood. Never reuse marinades unless they are cooked first.

Marinades should be mixed in a nonreactive container, such as stainless steel, porcelain, clay, or plastic—cast iron and aluminum are not acceptable choices. Plastic containers may pick up residual flavors of the marinade, and should be reserved only for the making of marinade in the future. Although food does not need to be completely submerged in the marinade, it needs to be turned often so its surface area comes into contact with the marinade. Food may be marinated far in advance, but after three to six hours there is no perceivable difference in penetration of the marinade into the food. Generally, marinades coat only the outer few layers of the meat. Immersion of foods for an overly long period results in an overly broken down piece of meat, cooked seafood, or macerated fermenting fruit.

#### Components of Marinades

Marinades have three main components, acids, aromatics, and fats. The combination of the three can show a distinct ethnic profile.

**Acids.** Acids include all types of vinegar, fruit juices, and cultured milk products, such as yogurt. Flavored vinegars such as balsamic from Italy are used sparingly, adding top notes of flavor, while a hearty apple cider vinegar will add a robust flavor to a pork roast marinade. Wine and wine vinegar are common for European marinades, while rice vinegar is common in Asia for simple fish marinades. Citrus juices shine in marinades; the souring agents of lemon juice or pomegranate juice are common in the Middle East. Lime juice in Latin America is the base for *seviche*. In this case, the marinade actually "cooks" the fish or scallops, transforming the proteins in the fish to a cooked state while still retaining the texture of uncooked fish. Orange or grapefruit juice may be used for variation. Dairy-based marinades include well-known yogurt and spice mixtures for lamb in the Middle East, yogurt and

cayenne for India's *tandoor*, and buttermilk for catfish in the American South. Even Coca-Cola is a common marinade base for some barbeque sauces.

**Aromatics.** Aromatics add a distinctive character, with spicy, hot, sour, or sweet flavors. Chopped ginger will dominate in an Asian-influenced teriyaki marinade, along with lemongrass and soy sauce. Chinese-style marinades use ginger, green onion, and garlic. A *mirepoix* (finely minced onions, carrots, celery, and leeks in red wine vinegar) flavors French-style marinades. Herbs may be fresh or dried, such as parsley, bay leaf, oregano, allspice, and peppercorns; juniper berries are typical ingredients for game marinades. Strongly flavored condiments such as Tabasco, Dijon mustard, fish sauces, or Worcestershire sauces add intense bursts of flavor to the marinade. Chilies are the foundation for many Latin marinades, including ground chili powder, or the smoky *ancho adobo* chile. Latin marinades also feature large proportions of garlic, cumin, and lime juice.

**Fats.** The fats in a marinade seal in flavor and help to keep foods moist during grilling. Olive oil or oils with mono- and diglycerides penetrate deeper and faster. As with other recipes, the oils provide a clue to the regional and ethnic profile for the recipe. Olive oil is preferred in the Mediterranean and in the western United States. Heavy fruity olive oils are best. Flavored nut oils such as hazelnut or sesame oil provide a balance to the acids and aromatics.

Yogurt, which has an acid component, also provides fat; it is one of the simplest marinades to create and use. More complex marinades will consider the balance between the right acid, aromatic, and fat. A heavy fruity olive oil will not balance light rice vinegar. Nor should the cook use strongly flavored oil such as sesame oil in large quantities. Sesame oil, like balsamic vinegar, is used lightly.

Since marinated foods are grilled over heat, the combination of fat and acid is needed when grilling to prevent the food from burning off the marinade combination before the food is properly cooked. During grilling, a chef will often use a basting brush to continue to coat the grilled food with reserved marinade as it cooks. Even the brush can be part of the art of marinade; rosemary sprigs can become a basting brush while adding additional flavor. As the marinades cook on the surface of the meats, caramelization and a slight glazing of flavors is produced on the surface as well.

### Consistency of Marinade

Marinades may be quite liquid, as in the classic red wine, olive oil, and rosemary-garlic marinade. They may also be thick and viscous, as in spiced cumin yogurt. Drier pastes are also marinades, and somewhat easier to spread over large pieces of meat. Jamaican jerk seasoning is thick, textured, and often features the intense heat of a scotch bonnet pepper. Blended with allspice, cinnamon, nutmeg,

brown sugar, and vinegar, jerk is a memorable marinade now used by gourmets. *Chimichurri* is a famous thick sauce-paste from Argentina, using cayenne, parsley, sherry vinegar, and lemon. Indonesian *sambals* grill strips of meat covered in a thick peanut and chili marinade. North Africans are familiar with Berber spice paste, with top notes of cumin, cinnamon, lemon, and olive oil.

Dry rubs are another marinade version. Rubs are a combination of spices, sugars, and salts spread onto the meat. The meat then basted with oil before grilling.

As long as the three components of marinades are kept in mind, many marinades are possible. A simple marinated chicken breast can transport the diner's palate to desert India with the use of *tandoor* marinade; to sultry Jamaica with Caribbean jerk; to sunny and sophisticated Provence, with garlic and rosemary; or to a down-home Texas barbecue, with chilies. Marinades can enhance the simplest ingredients, elevating them to a novel dining experience.

**MARKETING OF FOOD.** In order to understand how food is marketed in grocery stores or in restaurants or other food outlets, it is important to understand how consumers make choices among food options. It is generally believed that, although consumers sometimes have strong, stable preferences for some foods—for example, one may have a clear, unambiguous preference for sardines over and above any other food—more often than not, consumers' preferences are constructed on the spot and are contingent on a variety of factors, such as the social context, the other choices available, or the decision-maker's consumption goals. Therefore consumers do not always choose the same brands, or the same products, each time they go to the store. In this kind of decision context, marketing stimuli can be very effective at persuading consumers to buy one brand over another. In particular, the packaging and the branding of foods can be influential in how consumers choose among food items.

## Packaging Strategies

There has been a great deal of research done on how packaging influences consumers' perceptions of products. The first research in packaging was done in the 1930s when self-service supermarkets were becoming more popular. At this time, marketers placed *identical* detergents in two different packages: one had circles on the outside and the other had triangles. The marketers asked consumers which product they preferred and why. Eighty percent of the consumers preferred the product in the box with circles because they believed it had "higher quality." Even when the consumers took the two boxes of detergent home and used both products, the belief that the one in the box with circles was of higher quality persisted. This example points out an important aspect of the marketing of food: it is the perception of quality, not the actual quality, that influences consumers' decision making.

The packaging can influence a consumer's decision about what foods to choose even more than the taste of the product in some cases. One aspect of packaging that is very influential is the package shape. One of the most successful campaigns has been the Absolut Vodka campaign in which the shape of the distinctive Absolut Vodka bottle is featured in all of its advertising. Whereas some people may not be able to differentiate among the tastes of vodka in a blind taste test, they can easily differentiate between the different packages. Coca-Cola has also been successful in creating a distinctive bottle shape that influences perceptions about the taste of their product. One of the most famous bottle shapes is the Heinz ketchup bottle, which has been called the "best-known bottle in the world." The irony in this shape is that it is not really conducive to the use of ketchup as it is difficult to get the product out of the bottle. Heinz however used this difficulty as a positive feature in their advertising by promoting "ketchup races" in which being the last one to come out of the bottle was perceived as an advantage because it indicated the ketchup was very thick.

During the 1990s, Campbell's was concerned about decreasing sales of the company's soup. The marketing department did research to try and discover how to increase consumers' interest in their soup. Their research indicated that new soup in the old package would taste the same, but familiar soup in a new can would taste different. So Campbell's redesigned the label on their soup cans. The familiar red and white Campbell's soup can (made famous by Andy Warhol) was changed so that the red banner was thinner and a photograph of the soup in a bowl was placed on the white banner on the can. In fact, Campbell's was so convinced that the new labeling, rather than a change in the soup, would be a decisive factor in persuading consumers to buy their soup again that they declared right on the can, "New Look, Same Great Soup."

## GROCERY SHOPPING ON THE INTERNET?

Although there has been a great deal of interest in the United States in trying to make grocery shopping on the Internet a viable concern (for example, Webvan, HomeGrocer.com), few companies have been able to make it profitable. Part of the problem is the delivery of the groceries. In most residential areas in the United States, delivery locations are too far apart, meaning a truck can waste a great deal of time driving from one neighborhood to another. In order to make this kind of arrangement profitable, grocers will need a 25 to 30 percent gross profit on each order as well as average orders over \$100. This just has not occurred yet in the United States, and the firms such as Peapod and Webvan that have tried to make it work have not been profitable so far.

One retailer that has made it work is Tesco in Britain. Tesco is Britain's biggest grocer with more than 650 sites; they have said that their online grocery site, tesco.com, was profitable in 2000. Tesco allows its consumers to make their decisions online, and these orders are then sent to the store nearest the customer, where a store employee picks out the items ordered. Once the order is assembled, vans carry it to the customer's house. Orders average sixty items, and perhaps surprisingly, the most popular items purchased in this way include fresh fruit and vegetables (*not* bulk items such as laundry detergent). Tesco reports that in 2000, its online business represented one percent of its total grocery business.

If a model does become viable in the United States, we can probably expect online shopping to differ from shopping in a physical locale. Online consumers can sort their purchases much more easily and are not constrained by the physical layout of the store. For example, when shopping online, consumers can sort by price or nutritional information or create a list of products that were bought last time. These conveniences could potentially make grocery shopping a more efficient and more enjoyable endeavor. On the other hand, the flexibility of layout on the Internet can also help marketers to position their products in such a way as to increase the likelihood of consumers' purchasing them. For example, more packaging or advertising information could potentially be made available online.

## Framing Strategies

Another aspect of marketing that influences consumers' perceptions about the food, which in turn affects consumers' choices, is how the product is positioned or

## GROCERY CART

The grocery cart was invented in 1937 by Sylvan N. Goldman for his Standard Food Stores in Oklahoma City, after he noticed that shoppers would quit shopping when their hand-carried baskets became too heavy. The grocery cart on wheels was a stroke of genius in food marketing: It promoted greater sales, led to greater efficiency, and saved on labor costs. It was the start of self-service.

Before the grocery cart, food store merchants kept food on floor-to-ceiling shelves behind counters; a clerk was needed to assist customers with each purchase. Using the shopping cart, customers could select food items directly from "gondola shelves" set across the floor space, lowered so they could reach the top shelf and set just far enough apart for two shopping carts to pass between them, and fill their basket themselves. The width of the carts determined the width of the aisles in supermarkets.

The first cart was a folding cart with two baskets one above the other. Initially, the carts reminded women of pushing baby buggies; men eschewed them thinking they were strong enough to carry groceries by themselves. One of the early models of a shopping cart is enshrined at the Smithsonian Institute.

Once shopping carts caught on, they changed forever the way people shop and the way stores are laid out. By the late twentieth century grocery carts had increased in size and took on various configurations. They came in metal and plastic, some with special seats for children and some motorized for handicapped shoppers. Grocery stores on two or more floors have carts with locking wheels to allow them to be taken up or down moving ramps between floors. Some department stores are experimenting with nylon mesh carts.

In 2001, a cart cost around \$100 apiece in the United States and an average supermarket owned about 300 carts; at least 9.6 million grocery carts were in service (Weir, p. 37). In urban neighborhoods people would use them to transport their purchase home. Shopping

carts are also commonly seen on the streets of big cities being used by homeless people as "portable households." Strategies to prevent the loss of carts include imposing fines on anyone found with a cart off the store premises, locking carts together with a small device that releases a cart when the customer inserts a coin, and installing electronic sensors around the perimeter of store parking lots or at the store's exit doors. These sensors detect when a cart is about to leave the premises and lock the wheels, making the cart impossible to remove.

The shopping cart is a symbol of a consumer-led economy that is fueled by an affluent and mobile society. It is a piece of equipment that has become part of the distribution system of goods between manufacturers and consumers. It allows consumers to expand their purchases until the cart is full, wheel them in the cart to their cars, and drive them home. It also changed the need for labor in stores and allowed mass merchandising to the masses. As Terry Wilson wrote in 1978, it is "the cart that changed the world."

*Jean D. Kinsey*

framed. Ground beef that is 75 percent lean beef and 25 percent fat can be labeled either way: as 75 percent lean or 25 percent fat. Although these alternative labels convey the same information, however, they will not affect consumers' perceptions about the product equally. Studies showed that labeling the beef as 75 percent lean as opposed to 25 percent fat increases sales. The framing of the product can even be implicit. For example, the placement of a product in a certain aisle in the supermarket can affect the framing of the product. Consider Guiltless Gourmet Tortilla Chips. Placing this item in the regular chip aisle suggests that the product is a low-fat, per-

haps worse-tasting, alternative, compared to the other chips. Placing the same product in the health food aisle suggests that the product is a better-tasting snack as compared to other alternatives.

### Supermarket Layout

In general, the physical layout of the supermarket can also affect consumers' food-shopping decisions. Everyone knows that many supermarkets place high-demand items such as milk in the back of the store so that consumers are required to walk through the entire store and perhaps purchase extra items. Similarly, marketers can

The original shopping cart consisted of two baskets attached to a frame with a handle and wheels. This woman is seen using one of the early models in a self-service store in the 1950s. © BETTMANN/CORBIS.

use cross-merchandising techniques in the supermarket to try to influence decisions. Cross merchandising is a promotional technique that ties a promotion for one product to the promotion of another. For example, Duncan Hines might include a coupon for its frosting in a cake mix box, or Rice Krispies might include a coupon for Marshmallow Fluff in its cereal box. Similarly, in the physical store, marketers can link together certain items to encourage purchase. For example, higher-priced salad dressing might be located closer to the fresh produce, or a coupon for one product might be located on the shelf of another, higher-traffic product category. In another example, an in-store coupon for a health and beauty aid product could be located in the high-traffic bathroom tissue aisle. Some of these cross-merchandising strategies might be even more effective if consumers begin shopping for groceries on the Internet.

### Branding Strategies

Another aspect of food marketing that can very much affect consumers' decisions is branding. From the consumer's point of view, a brand name is generally a strong influence on purchase if three elements of the brand name are in place. First, the consumer must have a positive

evaluation of the brand name. Second, the brand name must be easy to remember and strongly associated with the product category. The ease with which the name is remembered when a consumer thinks of a category will depend on the frequency with which the consumer has seen the brand associated with the category, how recently the consumer has seen the brand, and the salience of these connections for the consumer. In addition, a strong association with the category will depend on how similar the brand is to others in the category and also how prototypical the brand is to the category. For example, Coke is seen as a prototypical soft drink and thus will easily come to mind when the category "soft drinks" is evoked. Finally, the brand image and evaluation must be consistent over time. In particular, a very strong brand name is one in which a consumer holds favorable associations that are unique to that brand and that imply some kind of differential advantage over other brands.

One of the strongest brand names in food marketing is the Coca-Cola brand name. After years of advertising and marketing, Coke also has a very strong, clear, consistent brand image—therefore, consumers form clear associations with it. For example, consumers may recall the packaging (the distinctive bottle or the red can), the taste of the product, or the current advertising appeals—for example, "Coke is the real thing." It is thought of as a "fun drink." Coke is also positioned as a different drink than Pepsi or its other competitors. Finally, and perhaps most importantly, Coke has a clear emotional bond and relationship with its customers. Coke learned just how important that brand name was in 1985 when they considered taking the old Coca-Cola product off the grocery shelves and replacing it with "New Coke." This prompted strong consumer reaction. Consumers felt that Coke violated something that was "theirs"—they felt that the Coke brand name belonged to its consumers and that Coca-Cola could not remove this classic icon from the market. Coke eventually returned "Classic Coke" to the marketplace to the delight of its customers.

Brand names can also influence consumers' perceptions of new products. If a marketer puts a familiar brand name on a new product, for example, Oreo cookie ice cream sandwiches, the consumer immediately knows something about the product even if she has never seen it before. Marketers are usually very careful about which new products they support with existing brand names as sometimes these brand extensions can backfire. For example, although Miller Lite was a very successful brand extension because the new light beer was instantly recognized and adopted in the marketplace, the new light brand had a negative effect on the main Miller High Life brand by causing consumers to think the original brand was less hearty.

In conclusion, sometimes when consumers go into the supermarket or into a restaurant to buy food, they have clear preferences for the foods they are buying and

## SENIORS FARMERS MARKET NUTRITION PROGRAM

The Seniors Farmers Market Nutrition Program (SFM-NPP) is a new program established by USDA's Commodity Credit Corporation (CCC). Under the program, CCC makes grants to states and to Indian tribal governments to provide coupons to low-income seniors that may be exchanged for eligible foods at farmers' markets, roadside stands, and community-supported agriculture programs. USDA CCC awarded almost \$15 million in grants to thirty-one states and five Indian Tribal Organizations for the new program. State departments of agriculture, aging, and health and tribal governments administering the grants have developed creative partnerships. They are utilizing existing infrastructure to offer farmers' markets the opportunity to expand to serve seniors and to certify and distribute benefits to the estimated 370,000 low-income seniors this pilot is expected to serve.

are not influenced by the food packaging, merchandising, branding, or promotion. However, more often than not, food preferences are not that stable and are constructed on the spot. In these cases, what consumers end up buying can be swayed by marketing cues in the environment such as labeling, branding, and packaging.

## MARKETING OF FOOD.

### ALTERNATIVE (DIRECT) STRATEGIES

Direct marketing refers to the strategy in which the producer of a commodity sells that commodity retail, directly to the consumer or end-user, rather than through a broker, distributor, or wholesaler. Direct markets for producers of food commodities include roadside stands, pick-your-own, farmers' markets, community-supported agriculture, mobile marketing, and mail-order sales. The supply of many food products through direct channels will fluctuate in accordance with the local harvest calendar. This is particularly true for fresh fruits and vegetables and less so for other foods, such as milk and milk products, eggs, meats, fish and poultry, grains, beans, and cereals.

In the United States, direct marketing continues to grow as a method for small- and medium-sized producers to increase their profits. Several forms of direct marketing—farmers' markets, roadside stands, Community Supported Agriculture (CSA) farms, and pick-your-own operations—have accounted for most alternative marketing strategies. Newer forms, such as "farm-to-school" connections and Internet marketing, are also being developed and piloted in many locations through the United States. Direct marketing data from the Census of Agriculture showed that between 1992 and 1997, the

number of farms involved in direct marketing increased 7.8 percent to 93,140 farms. The total value of direct-marketing sales and direct-marketing sales per farm also increased.

"Alternative" or direct-marketing opportunities are part of a new agriculture that is being referred to as civic agriculture. The name suggests a locally based agricultural and food production system that is tightly linked to a community's social and economic development and to enhancing social capital. While civic agriculture may not represent a challenge to the conventional agriculture and food industry, it does include some innovative ways to produce, process, and distribute food. Additionally, the connections and relationships that are possible between producers and consumers from these marketing channels are unique to community-based food systems and civic agriculture.

Several factors have led to a growing consumer interest in purchasing directly from farmers: desire for fresh, high-quality products, the ability to personally interact directly with farmers who grew/raised the food, and interest in supporting local, small farms. Availability of product information such as growing method, instructions about use, recipes, and taste samples also draw customers to direct-marketing outlets.

### Farmers' Markets

Farmers' markets, now an integral part of the urban/farm linkage, have continued to rise in popularity, mostly due

Apple vendor along the Lee Highway in Shenandoah National Park, Virginia, 1935. COURTESY OF THE LIBRARY OF CONGRESS.

to growing consumer interest. The number of farmers' markets in the United States has grown dramatically, increasing 63 percent from 1994 to 2000. According to the 2000 National Farmers' Market Directory, nearly 3,000 farmers' markets now operate in the United States. This growth indicates that farmers' markets are meeting the needs of an increasing number of farmers with small- to medium-sized operations. Small farm operators benefit most from farmers markets—those with less than \$250,000 in annual receipts who work and manage their own operations meet this definition (94 percent of all farms). Farmers' markets are also an important source of revenue. In the 2000 USDA Farmers' Market Study, 19,000 farmers reported selling their produce only at farmers markets. Communities also benefit from farmers' markets. Dollars spent on food are recycled several times within the community and thereby help boost the local economy.

Farmers' markets also serve an important role in increasing community food security. In many urban centers where fresh, nutritious foods are scarce, farmers markets increase the availability and access of these options for segments of the population that need them most. Farmers' markets also help to provide nutrition education, focusing on selection, storage, and preparation of a wide diversity of fruits and vegetables. Nearly 60 percent of markets participate in WIC Farmers' Market Nutrition Program, most accept food stamps (although the development of electronic benefit transfer [EBT] will make

this difficult at many markets) as well as other local and/or state nutrition programs. A quarter of all farmers' markets participate in gleaning programs aiding food recovery organizations in the distribution of food and food products to needy families.

USDA's Women, Infants, and Children (WIC) Farmers' Market Nutrition Program (FMNP), established in 1992, provides additional coupons to WIC participants that they can use to purchase fresh fruits and vegetables at participating farmers' markets. The program has two goals: To provide fresh, nutritious, unprepared, locally grown fruits and vegetables from farmers' markets to WIC participants who are at nutritional risk; and to expand consumers' awareness and use of farmers' markets. Fiscal Year 2000 federal funding for the WIC Farmers' Market Nutrition Program was \$15 million. The FMNP operates in thirty-nine state agencies, including four Indian tribes, one territory, and the District of Columbia.

### Roadside Stands

Roadside stands or markets are a type of direct marketing system where a grower establishes a selling place (stand) near a roadway and sells produce directly to consumers. Often a stand is located on a farm or orchard. Produce sold in a roadside stand may be grown exclusively on the farm or may be purchased from outside sources. A roadside stand may be open only during harvest periods or throughout the year, depending on produce supply sources.

Direct marketing of food products is an age-old practice designed to eliminate middlemen. This Persian illumination from 1540 shows an Iranian butcher selling his cuts of meat from a stand along the street. © BURSTEIN COLLECTION/CORBIS.

To producers, a roadside stand often represents a supplemental source of income, additional employment for family members, and a way to market surplus produce. Besides measurable financial benefits, producers establish relationships through direct exchange with customers. These relationships provide critical feedback to farmers when making planting decisions, developing customer education, and developing marketing strategies.

Roadside stands allow direct market sales without off-farm transportation costs, although some stands are located off the farm to get closer to traffic volume or population centers. Generally, marketing costs depend on the size of the retail outlet. These range from self-serve tables at the end of a driveway to pseudo-supermarkets with a huge selection of off-farm merchandise in addition of farm products. As volume, traffic, and product selection

increase, so too will stand size, operating costs, and management time.

### Pick-Your-Own Operations

This type of direct marketing, where customers come to the farm and harvest produce directly, is most common at fruit farms in the northeastern United States. As fewer families now “put up” (can, freeze, or otherwise preserve) large quantities of food, the “farm experience” has become a more important reason for people to pick produce at a farm.

### Farm-to-School Connections

Through the school meals programs during the school year and summer programs, schools, colleges, and universities represent a largely untapped opportunity to strengthen the market for farmers and increase access to locally grown, high-quality foods for young people. Such direct purchases are increasing through an expanding number of farm-to-school projects throughout the country.

### Direct Marketing as a Way to Build Civic Agriculture

Increasingly, alternative or direct-marketing channels are seen as engines for growth in civic agriculture. Since over 80 percent of the consumer food dollar currently goes to pay for the marketing bill, leaving less than 20 cents for every dollar for the farmer, direct marketing may be critical to the economic survival of agriculture.

**MEAL.** Academic interest in meals, while crossing many disciplines, is concentrated mostly in the fields of social anthropology and sociology. The premise of much of this research is that whatever broader historical and social influences on food and eating may be identified in any cultural milieu, the taking of food is more often than not organized around some concept of the meal.

### Historical Aspects

There is a modest literature that, while not focusing precisely on the meal, offers insights into the history of meals. Of undoubted importance is the reduction in the size of meals in Western civilizations. From the Roman poet Petronius's account of Trimalchio's feast in *The Satyricon*, through medieval banquets, to the gluttony of restaurant dining in France, the size of a meal in terms of the varieties and number of courses has declined, at least for the affluent social classes. One difficulty with historical studies of food and eating is their focus on aristocratic and bourgeois habits. This is perhaps unsurprising, as the diet of the poor appears to hold in variety and content less fascination, although John Burnett's *Plenty and Want* (1979) elegantly counters this view. Sociologist-historians like Norbert Elias maintain that the diminution in the number of courses represents a trend to civilizing taste through self-restraint such that the epitome of "good taste" is, crudely put, reflected in a "less is more" philosophy, and gluttony and excess is associated with the bestial side of human nature.

A second theme of interest is the impact on meal taking of industrialization, whose main consequences in the food arena include "improvements" in food production, preservation, and transportation, and the exploitation and

creation of markets for existing and previously unavailable foods. The growth of agribusiness and subsequent opposition to it has cast doubts on these supposed benefits of industrialized society.

What is perhaps less appreciated about the industrialization of food is the extent to which it has created and supported the embedding of male and female roles in the home and elsewhere. This leads, thirdly, to the profound effects of industrialization on patterns of family life. In the last quarter of the twentieth century, the demands of industrialization have seen greater female participation in the labor force in much of the developed world that, taken together with the increasing application of technology to the culinary sphere, has had implications for food consumption. This is reflected in debates about the decline of the meal and the rise of snacking, or grazing, which, in recent years, have been linked to broader ideas about the "McDonaldization" of food and eating.

### Functions of the Meal

No account of the role of the meal in society can ignore efforts to explain the apparent human need to dine communally. In a popular approach to understanding the nature of meal-taking, scholars have delineated five general functions of the meal and of feeding more generally. First, meals demonstrate much about the nature of status differences in society. The display and distribution of food as a means of demonstrating social status is common to many societies. The giving of food can be an act designed to heighten the status of donors by emphasizing the difference between them and the recipients of their largesse.

Second, whom one dines with and what one eats define social and status group membership and the closeness or distance of relationships between individuals. For example, a hot meal generally reflects closeness and intimacy and can be confined to immediate family and intimates (Douglas, 1972). Within the family, status and power differences determined by gender can be reflected in the distribution of food. Several researchers have demonstrated that high meat consumption is associated with men, and that women often give priority to male food preferences at the expense of their own tastes. In the workplace, class and status differences can be mirrored in a separate provision of food for managerial and related grade staff, and for "blue collar" workers (Murcott, pp. 45–53). Third, food has symbolic functions and meanings. Various forms of feasting serve to link individuals to the wider social fabric through shared understandings of cultural conventions (as, for example, with Christmas or Thanksgiving). Meals also offer opportunities for status symbolism, where food is a form of currency either literally (whereby animals are exchanged for goods and services), or through the medium of gift-giving (intended to elicit some reciprocal gift or service). Status symbolism is also conveyed in the case of dining out, in the selection by the host of a meal environment appropriate in its level of excellence and expense.

Fourth, meals give opportunities to demonstrate role performance. For a host, the meal allows demonstration of good taste and knowledge of what is relevant to particular dining situations. For all individuals, mistakes over etiquette and the actual eating of food can be embarrassing, discrediting a person in the eyes of others (for example, using the “wrong” knife or fork or employing the “wrong” terminology). Fifth, control of role performance is closely related to the role played by food in socialization. Meal times, as occasions when social groups are normally together, provide opportunities for the uninitiated—particularly the young—to observe what is acceptable in terms of food-related behavior. For children, meal times allow observation of what foods are routinely available for consumption and how these should be consumed; in other words, children are inculcated both formally and informally into matters of etiquette.

### Structures of the Meal

The observation that in many societies, food consumption is organized around some concept of the meal led much early sociological research to focus on the nature and meaning of meal structure. The pioneering work of Mary Douglas offers theoretical grounding of the study of food and eating in localized empirical studies of dining. In her article “Deciphering a Meal” (1975), she identifies two contrasted food categories—meals and drinks. Meals are structured and named events (for example, lunch, dinner) whereas drinks are not. Meals are taken against a background of rituals and assumptions that include the use of at least one mouth-entering utensil per head; a table; a seating order; and cultural restrictions on the pursuit of alternative activities (such as reading) while seated at table. A meal also incorporates a series of contrasts: hot and cold, bland and spiced, liquid and semi-liquid. Both meals and drinks reflect the quality of social relationships. Drinks are generally available to strangers, acquaintances, and family. Meals, by way of contrast, are reserved for family, close friends, and honored guests.

Douglas’s key empirical study with colleague Michael Nicod relates meal structure to meal content. Nicod recorded over various periods the dining patterns of four English working-class families, whose diet of the time centered on two staple carbohydrates—potatoes and cereals, in contrast to upper- and middle-class diets, which made greater use of a range of cereals, beans, and roots. Focusing on the type and cycle of meals within the domestic economy, Nicod identified three types of meal: Meal A, a major meal, served around 6:00 P.M. on weekdays and in the early afternoon on weekends; Meal B, a minor meal taken at 9:00 P.M. or 10:00 P.M. on weekdays and 5:00 P.M. on weekends; and Meal C, consisting of a biscuit and a hot drink. This last meal was a flexible component available at any time in the daily dietary cycle but most often taken both in late afternoon, on the return home of the principal wage earner, and before retiring for the night.

### Meal Content and Cycles

Of the three types, Meal A is accorded the greatest analytic importance by Douglas and Nicod. A strong correspondence between the weekday evening meal and the Sunday meal was apparent. In both instances, the first course was the main course, always hot and savory and based on a tripartite structure of potato, centerpiece (meat, fish, eggs, with one or more additional vegetables), and dressing—usually gravy. The second course repeated these rules of combination except that it was sweet. The staple took a cereal form (pastry, sponge), the centerpiece was often fruit, and the dressing custard or cream. On Sundays and other special occasions, the second course was often followed by a third consisting of a hot drink and biscuit(s). This third course maintained similarities in rules of combination in that a biscuit has a cereal staple form enclosing a fruit or cream-type filling. In one respect, however, the pattern differed, in that liquids and solids were totally separated, in contrast to other courses, and the structure was reversed in so far as the hot drink appeared in a cup or similar receptacle, whereas the cold biscuit was on a plate.

Thus, according to Douglas and Nicod, meals possess the following elements. First, they have rules of non-reversibility in the archetypal meal. Second, the order of food runs from savory to sweet and from hot to cold in terms of the principal food items consumed. Third, quantity decreases with each course as formal patterning of foodstuffs increases. Regarding the latter, Douglas sees the first course as fairly amorphous, but as a meal progresses, this gives way to increasing geometric precision and structure (Douglas, 1982; Wood, 2000).

### The “Cooked Dinner”

Whereas Douglas places equal emphasis on meal structure and meal content, it is the latter that has driven many subsequent and empirical studies of meal taking. Murcott’s (1982) study of thirty-seven pregnant women in South Wales is almost as important as Douglas’s work for the elaboration of a research tradition. Murcott found that the “cooked dinner,” an elaborated model of Douglas’s principal Meal A type, comprising meat, potatoes, at least one additional vegetable, and gravy, was regarded as a “proper meal,” and perceived as essential to family feelings of health and well-being. Structurally, the cooked dinner was thought of as a meal in itself, was heavy and large rather than small and light, and hot, never cold. Thus, although a succession of courses was permissible, the cooked dinner as centerpiece could, in contrast to sweet-based items, stand in its own right as a meal. Fresh meat was a priority, and potatoes were always specified and itemized separately from other vegetables. Certain meats had common circulation—beef, lamb, pork, chicken—whereas others, notably turkey, were reserved for special occasions. Fish was not regarded as an acceptable substitute for meat in the cooked dinner form. While potatoes were invariably a constant (roast on Sun-

day, usually boiled at other times), slightly more flexibility was evident in the choice of additional vegetables. Even here, however, certain rules appeared to operate. First, additional vegetables were almost invariably green and from “above ground” (typically peas, beans, sprouts, cabbage, and occasionally broccoli and cauliflower). Second, additional vegetables were prepared only in addition to these and were generally from “below ground” (for example, carrots and parsnips). Together with meat and potatoes, the final ingredient necessary to the structural integrity of the cooked dinner was gravy, last in the cooking and serving sequence, and poured onto the plate after other items had been assembled, an action Murcott sees as linking and transforming items in the cooked dinner into a coordinated whole. Cyclically, the importance of the cooked dinner to Murcott’s sample was emphasized in the fact that it was eaten on only three or four days of the week (including, invariably, on a Sunday) and thus had relative scarcity in the family dietary system.

### The “Cooked Dinner” in America

The British work of Douglas and others is echoed in various American studies, which generally support a view of meals as central to domestic dining systems. In a 1942 study of food habits in Southern Illinois, researchers found that food consumption centered on three staples: potatoes, beans, and pork. The authors term this the “core diet” and note that around the core was, first, a secondary core, consisting of many foodstuffs that had recently become available for purchase from local stores; and, second, a peripheral diet of infrequently used foods outside of the core and secondary core (Bennett et al., 1943). All three of these concepts are used in similar form by Nørge Jerome, who charts content variations found in meals and snacks for all of “normal” weekday meals, “Sunday dinner” and festive meals (for example, Thanksgiving). Jerome argues that the dietary order consists of core and staple items; secondary core items, which are added to or substituted for items in the core as circumstances and contexts vary; and peripheral dietary items, which are those items used infrequently, including ceremonial foods.

In a much more complex series of studies of Italian-American diet in Philadelphia, Judith Goode and various colleagues relate variations in the selection of different meal formats to meal cycles (food consumption patterns over time), community values, and activity patterns of households, building up a many-layered picture of the interrelationships between the role of food in people’s lives and other aspects of the social order (Brown, pp. 66–68).

### Gender and the Meaning of Meal Structure

For Douglas, the meaning of meal structure lies in its implications for family constitution. The patterning of food performs a regulatory function, encouraging family stability, a view with clear policy implications for dietary and nutritional intervention. For Murcott, an important

The construct or format of a meal varies greatly from one culture to the next. In this meal at Île de Gorée, Senegal, a family partakes of its food from a common bowl. © CORBIS (BELLEVUE).

symbolic feature of cooked dinners is the extent to which their preparation validates women’s roles in family and marital contexts: “If a job defines how a man occupies his time during the working day, to which the wage packet provides regular testimony, proper provision of a cooked dinner testifies that the woman has spent her time in correspondingly suitable fashion . . . the cooked dinner in the end symbolizes the home itself, a man’s relation to that home and a woman’s place in it.” According to Murcott, the overall responsibility for domestic affairs falls to the woman of the house, whose responsibility for the cooked dinner includes the process of accommodating family food preferences, especially those of the husband or male partner. Most women choose what food is purchased for family consumption, but, because of the need to balance factors such as family tastes and preferences, food cost, variety, and nutrition, this is often considered a burden rather than bestowal of authority to determine the domestic dietary cycle.

Second, women frequently subordinate their own food preferences to those of male partners. Men, especially if employed, are regarded as requiring food in quantity, and male energy needs are regarded as exceeding those of other family members and, in particular, of women. Researchers Nickie Charles and Marion Kerr found that very high consumption of meat was almost totally confined to men, while very low meat consumption was associated primarily with women and children. Several other studies have shown that women often go without food, particularly in families where there is financial hardship. Women’s voluntary denial is further reinforced by societal pressures to maintain “ideal” body weight and image.

Third, the “absence” of cooked dinners or a female to cook for men can disrupt the social fabric. Two very different examples of this are found in instances of domestic violence and of “womanless men.” Researchers have observed that the centrality of food in marital relationships can often lead to violence as men turn on

In contrast to the family scene from Africa, this image from Biedermeier Austria depicts the essentials of a midday meal during the 1840s. Nanny with baby, the kitchen maid bringing in a pudding, father carving the roast—all of these are visual clues that tell us that this meal in a well-off household is being eaten in several courses and that there is probably a pecking order in terms of who eats what. COURTESY OF THE ROUGHWOOD COLLECTION.

women for perceived failures in the performance of those tasks that are accorded them and that men usually learn domestic cooking and practice that skill only when they have no woman to cook for them (Murcott, pp. 164–171, 172–177).

### The Limitations of Structure

The investigations alluded to thus far are highly ethnocentric, useful for elaborating the parameters of the structural model of meal-based food consumption but limited in geographical scope. These studies also suffer from criticism of their over-reliance on evidence from studies of traditional working-class/blue-collar communities and families; an exaggeration of the extent to which women are the main providers and preparers of food, as these activities become much more democratically organized; and a failure to analyze the decline in meal taking and rise in snacking, or grazing.

### “McDonaldization”

Arguments supporting the decline of the meal have received impetus in the thesis of George Ritzer that the global fast-food franchise McDonald’s has been in the vanguard of the rationalization both of cuisine and of social life more generally. For Ritzer, the interplay between technology and food production has led to fragmentation of private and public food consumption. In fact, Ritzer’s early work on McDonald’s and “McDonaldization” is the

summation of an extensive literature on fast food arguing similar themes (Leidner, 1993). Implicit in Ritzer’s analysis is a view of American domestic cuisine at odds with research on the British experience. The relative absence, however, of parallel detailed studies of food in American domestic life makes it difficult to assess uniformity and diversity of the meal-taking experience in the United States.

### Restaurant Meals

It was noted earlier that social scientific study of food and eating is a relatively young and under-researched field. Nowhere is this more true than in the study of dining out. The early work of Campbell-Smith (1967) promulgated the concept of the “meal experience” whereby customer satisfaction in dining out was attributed to multiple environmental factors and not food choice and quality alone. This view is probably no longer tenable. Studies of the restaurant “meal experience” suggest that consumers prioritize available food choice, price, and quality when dining out. According to researcher Joanne Finkelstein, dining out is a mannered act in which the participants rarely derive much enjoyment, since the very act of engaging in restaurant dining entails consumers subordinating themselves to the rituals and imperatives of the establishment, a condition Finkelstein calls “uncivilised sociality.” Her analysis has attracted supporters (see Wood, 1995), but also detractors, whose own multi-method studies emphatically show consumer control and

enjoyment of dining out. They also reject the arguments of theorists who argue that domestic dining and dining out have increasingly converged.

This convergence takes the form of public menus reflecting more and more the structured dining of the home with greater similarity of offerings and a concomitant overall reduction in the choices available to consumers. This “interpenetration” of private and public dining is supported by advances in technology, which have increasingly allowed foods eaten in the public domain to be purchased at the supermarket and consumed at home. Warde and Martens (2000) at least partially reject this view, instead concurring with Mennell (1985) that increasing variety is indeed a feature of public and private dining and claiming that writers such as Wood have exaggerated trends in convergence and the reduction of choice. This is despite finding some evidence of considerable similarities with domestic food consumption in the structure of meals taken outside the home.

### Public to Private Again

Warde and Martens’s arguments are often contentious but they set the pattern for future explorations of Western public food consumption in empirically grounded studies of actual consumer behavior. At the same time, a note of caution can usefully be sounded. The concept of meal and related structures as described in this article have for the most part been empirically demonstrated by reference to Anglo-American standards. Yet, similar structures (such as the centerpiece, carbohydrate staple, and dressing) compose many meal formats around the world even if they do not precisely mirror the “cooked dinner.” Variation may not, in fact, be so great, since many cultures follow the stew or “ragout” model, combining centerpiece and dressing, and sometimes combining these with a carbohydrate staple (such as curries or certain pasta dishes), while others observe the carbohydrate “base” model (as found in pizzas, tacos, fajitas), where food is placed on the staple or enclosed within it.

Through the work of theorists of the latter half of the twentieth century, a social scientific study of the meal has emerged and, employing various models of structure, has advanced considerably. But many more diverse empirical studies remain to be done before we can gain confidence in any assertions about this fascinating and fundamental aspect of human existence.

**MEALS ON WHEELS.** A change in the 1965 Older Americans Act (OAA) allowed prepared meals to be delivered to qualified individuals assessed to be homebound or otherwise isolated. In 1972 the OAA, which initially addressed the needs of the elderly to promote independence and successful aging, was amended to include nutrition. Federal funds were allocated for local

Meals on Wheels specializes in providing daily meals for shut-ins, especially the elderly. PHOTO COURTESY OF AP/WIDE WORLD PHOTOS.

communities to provide hot meals in group dining situations for persons over sixty years of age and their spouses, regardless of the spouse's age.

For those senior citizens who were unable to prepare adequate meals for themselves or attend the congregate nutrition centers because of ill health or physical incapacity, the first so-called meals-on-wheels program was established in Pennsylvania. Volunteers dubbed "Platter Angels" prepared, packaged, and delivered meals to homebound elderly in the community.

As the demand for the service continued to grow, additional neighborhood meals-on-wheels programs sprung up across the country. Volunteers organized programs and delivered meals. A fee was charged to cover the cost of food and preparation. Charitable institutions such as churches and civic organizations were called upon to subsidize costs for those unable to pay.

Although limited federal funds were available to the volunteer programs, Congress recognized that a major federal effort was needed. Another change to the OAA in 1978 (Title IIIC-2, Home-delivered nutrition services) provided for the home-delivered meals for those assessed as unable to participate in the congregate meal program. Administered by the U.S. Department of Health and Human Services Administration on Aging, the program focuses on those in greatest economic and/or social need.

By requirement, each home-delivered meal must supply at least one-third of the Recommended Dietary Allowances for this age group. It is estimated that 40 to 50 percent of most required nutrients are supplied in practice. Guidelines developed to assist in menu planning indicate both the types and the amounts of food to be included in each meal. Some state programs have chosen

to offer additional services such as offering medical nutrition supplement products. Delivery packaging materials for the meals should be safe and acceptable for both hot and cold foods, they should prevent contamination, and be reasonable in cost. Improper handling by recipients leading to food safety issues has been raised as a concern. Evaluation studies of program effectiveness affirm that the nutrient-dense meals improve the status of the homebound.

Thirty percent of the cost of the home-delivered meals is met through OAA funds. Public and private partnerships leverage additional resources. Every \$1 in federal funds leverages an additional \$3.35 in the home delivered meals program. The demand for homebound meals has dramatically increased in concert with the growing number of frail and homebound elderly who want to remain independent. Based on the most recent figures, about 135 million home-delivered meals are served annually. From the program's inception more applicants were attracted than could be accommodated, and waiting lists in many areas are not uncommon.

A separate but similar national organization that complements the federally supported home-delivered meal service is the Meals-on-Wheels America (MOWA) program. Their additional home-delivered meal service is seamlessly integrated into existing meals on wheels programs. Meals-on-Wheels America helps local communities raise funds and expand their nutrition programs for homebound elderly.

With the elderly population expected to double by 2030, senior feeding programs such as meals on wheels will continue to provide much-needed ongoing services.

**MEAT.** For most human beings, meat is a highly desired food, but it is more of a treat than a staple. Meat, whether obtained from hunted or domesticated animals, is more expensive than staple carbohydrate-rich foods because of the investment in land and labor required to produce it. This reality is often the justification for reserving meat, or the best parts of it, for those with higher status.

In a majority of the world's cultures, this elite is men and, sometimes, the women and children attached to them. Furthermore, when there is enough meat to go around, the preferred parts, usually the muscle, go to these same individuals.

It is this special status of meat that makes it of particular interest in human culture, psychology, and cuisine. Meat is also the only class of food that is frequently formally proscribed by certain religions, cultures, or cultural subgroups.

### **Ambivalence and the Psychology of Meat**

The stakes are high with meat. Meat is both the most tabooed—and the most favored—food across the human race, in both developed and traditional cultures. Meat is a magnet of ambivalence for human beings. It is meaningful, in both the positive and negative sense. Eating meat is both attractive and repulsive. Hunting, too, is problematic. It is a skilled accomplishment at the same time that it is a destructive act. Meat provides a food for humans that is more similar to humans than any other type of food. The similarity means that the biochemical composition of meat is much like that of humans, so that, by eating it, humans get all the nutrients they need. The meat of any mammal is a complete, or almost complete, food, in contrast to vegetable foods. But this similarity means that microorganisms living in the meat are also likely to find a happy home in humans. Meat is thus the most nutritive and most infective food humans eat.

### **You Are What You Eat**

It is quite natural and sensible to believe that a person takes on the properties of the food he or she eats. In general, when A and B are mixed, the resulting product shows properties of both A and B, so why should this not occur when A eats B? The problem, of course, as understood through the lens of biochemistry, is that after digestion the components of various foods, foods as different as beef and bananas, are the same molecules: amino acids, sugars, and so on. From this perspective, the identity of an eaten food is lost by the time it is digested. Nonetheless, the belief remains, and it is present in the thinking of almost every traditional culture. This “principle” is behind such notions as eating owls improves vision, eating swift animals increases running speed, eating rapidly growing plants speeds up growth, and the appearance of foods, including their color, can influence humans' appearance. “You are what you eat” is not just a primitive superstition; it is believed, implicitly, by educated people in technologically advanced cultures.

It follows from “you are what you eat” that the consumption of animals will impart some of their animal properties to the person consuming them. Although many animals have desirable attributes, they all share the property of not being human. And it is a major theme, across cultures, that humans are superior to, and qualitatively different from, animals. Yet, consumption of an-

Samaritans sacrificing and roasting lamb at Passover on Mount Gerizim near Nablus, Israel. © DEAN CONGER/CORBIS.

imals, according to the “you are what you eat” principle, would render humans more animal-like, that is, less distinctively human. This belief contributes to human ambivalence about eating meat, and may partially account for the disgust aroused by animal foods in some people.

### **Meat and the Human Primate**

Primates show substantial variation in the types of diets they consume; however, there is a general focus on fruits. Some, particularly large primates, move to a more folivorous (leaf-eating) diet, and some consume a moderate amount of small animals, including insects. The larger stomachs and colons that characterize folivorous animals contrast with the smaller colons and stomachs of the carnivores. Frugivores (fruit eaters) typically have a gut that lies between the carnivore and the folivore extremes, and this is what humans have. This type of gut, and the associated general-purpose set of teeth, are well suited to generalist or omnivorous feeding habits, which characterize humans and chimpanzees. Humans can be distinguished from other primates, including chimpanzees, in their ability to hunt animals larger than themselves. This hunting capacity, related to the movement from the forest to savannah environment, has major implications for human nature and human evolution. First, it introduces the possibility of a substantial amount of meat in the diet.

Native American method of drying meat on racks. PHOTOGRAPH BY EDWARD S. CURTIS, 1908. COURTESY OF THE LIBRARY OF CONGRESS.

In addition, the demands of hunting encourage elaborate communication and cooperative effort as well as the creation of weapons and the technology that goes with them. The yield that results from killing a large animal encourages sharing, communal eating, and preservation technologies. It is fair to say that the shift to a diet with more meat in it, with the inclusion of large animal hunting, was a major force in human evolution. In an important sense, meat as food has shaped human nature.

### Meat in Traditional Society

It is presumed that the hunter-gatherer mode of existence, with varying degrees of reliance on vegetable and animal products, was the situation of *Homo sapiens* prior to the appearance of domestication and agriculture. However, this should be recognized as a presumption. Studies of the diverse range of existing cultures that rely to a large degree on hunting and gathering suggest that meat, even at this stage of human cultural and biological evolution, assumed a central role. Meat is generally the favored food, the center of celebrations and social gatherings, and the food selectively available to adult males, the most powerful and high-status members of most hunter-gatherer societies. This situation probably results from a combination of the caloric density of meat and the fact that meat, unlike any particular vegetable, is a

complete food. On the other hand, the relative rarity of meat, which usually constitutes much less than half of the diet, encourages rules for its selective distribution.

Even among hunter-gatherers, however, there are signs of ambivalence to meat. Most food taboos of hunter-gatherers, and they are extensive, are about meat. Taboos are sometimes general, namely that certain types of animals are forbidden as food. On the other hand, most taboos are conditional, restricting the eating of meat, or certain parts (muscle, innards) to particular groups. Generally, the adult males get the greater amount of meat, get to eat the preferred animals, and get the preferred parts (usually muscle). But there are many exceptions to this general rule. Meat or animal taboos, whether in hunter-gatherer or technologically developed cultures, seem to have a few general characteristics. In what has been referred to as “zones of edibility,” tabooed creatures tend to be those very close to humans (humans themselves, primates, or companion animals), those very different from humans, and/or those that are rarely encountered.

### Domestication

Meat figures prominently in what might be called the two most important transitions in human evolution: the development of complex cultures and sophisticated tech-

nologies. Just as hunting had a major influence in shaping human nature, the combination of agriculture and domestication laid the foundation for high densities of humans and the subsequent elaboration of culture. By making the human food supply more independent of the seasons and of short-term extremes in weather, agriculture and domestication set the stage for major changes in human life. Domestication made it possible for humans to be the only mammals that could have continued access to the almost perfect mammal food of infancy, milk; it also frequently made meat a less scarce resource. Just as hunting helped encourage the upright posture, the development of hand skills, and major cognitive developments, agriculture and domestication of animals freed humans to develop a wide range of impressive technologies.

### Meat in Developed Societies

The tables have begun to turn on meat in today's affluent, developed world. The excitement of meat hunting has given way to factory farming. The butchering of the carcass takes place out of sight of almost everyone, so that the skills involved in butchering as well as hunting are almost gone. The caloric density of meat has lost much of its appeal because the threat to human health is too many calories, rather than too few. Similarly, the nutritional completeness of meat is a less salient virtue, what with the great variety of plant foods available in any neighborhood supermarket. The epidemiological revolution has shifted health risks from minimal diets, unbalanced diets, and infections spread by humans through food and other products, to degenerative diseases like heart disease and cancer. And animal fat has been implicated as a risk factor for heart disease. Finally, the affluence of modern societies permits the development of great sensitivities to nature and the morality of using animals as food; with many options available, it is possible to allow moral concerns to influence diet. Vegetarianism is on the rise, for both moral and health reasons, and many of the nonvegetarians in the urban developed world are queasy about the actual process of killing animals. This attitude appears even in the slaughterhouse itself, where responsibility for killing the animals is diffused across a number of different people and roles. In Britain, the United States, and Canada, the human approach to meat has become increasingly ambivalent. The human primate still loves the taste and smell of meat, while cultural knowledge and sensitivities argue against it.

### Disgust

Disgust is a powerful emotion, and animal products often arouse it. Almost all foods that are labeled as disgusting in a number of cultures are of animal origin. It is odd, because "dis-gust" means 'bad taste', and meat is one of the best-tasting foods to humans. It is odd also because, given the superior nutritional properties of meat, it should not be the target of the strongest negative food-related emotion.

Meat preference may be a human predisposition, but it is probably not present in infants. Ironically, there may be some predisposition to find meat disgusting, but this as well is not present in the first few years of life. Human infants eat, or at least try to eat, everything they can get into their mouth. Feces, the universal core of disgust, and itself an animal product, is attractive as a food to human infants, as it is to other young and adult mammals. Presumably the odor of decay, associated as it is with microorganism-infested meat, would be innately repugnant, but there is no evidence for an infant aversion to this odor. Nor is there evidence for such an aversion in other primates or mammals. By age two or three, in Western developed cultures (which have provided all of the data up to this time), children have a clear aversion to feces, and a variety of other animal products, especially those that are decayed. This is probably the result of toilet training, although there is no account available of the actual process through which this aversion to feces and decay is aroused.

The foods that are disgusting to adults, cross-culturally, are almost entirely of animal origin, beginning with feces and, for Americans, extending widely to many of the edible parts of animals. Indeed, considering all of the possible animal foods (insects, mollusks, reptiles, amphibians), it is quite remarkable that Americans consume only four or five species of mammals, a few species of birds, no amphibians and reptiles, a moderate number of the many species of fish, only a few types of shellfish, and no insects. Furthermore, the meats eaten by Americans exclude many parts of edible animals; consumption is almost exclusively limited to muscle, and, in general, not the heart or tongue, although these are muscles. So far as is known, this idiosyncratic selection of animals and animal parts as acceptable food has no nutritional or health basis.

These facts lead to the conclusion that disgust at animal products, and the avoidance of most animal products, has an ideational base; it is based neither on taste (most of the "disgusting" types of meat have never been tried) or actual health risks. It is the *idea* of eating lizards, cow eyes or intestines, or insects that is upsetting and expressed as disgust, somewhat parallel to the formal taboos in other cultures against the consumption of many types of animals or animal parts.

Humans are clearly adapted to a partial meat diet and to liking the taste of meat, especially when it is cooked. But there are some negative sides to meat eating. Perhaps most important is the threat of microbial contamination; because animals are more like humans than plants are, animals are more likely to harbor microorganisms that can afflict humans. This microbial load also makes animal flesh vulnerable to decay after death. Many have argued that the use of many spices originated as a culinary means of discouraging spoilage of meat. During the twentieth century most of the microbial risks were overcome with controlled raising, preparation, and storage of meats. However, as feeding a population of

## SAFE MEAT PRODUCTION

With the appearance in the 1990s of bovine spongiform encephalopathy (BSE; more familiar to the public as “mad cow disease”) in England and France, and the deaths caused by its spread to humans who ate meat from diseased cows, vigilance with respect to safe meat production became even more critical. In spite of research demonstrating that the disease had been spread in herds that had eaten feed that contained meat products, some feed suppliers in the United States were found continuing the practice in 2001, and, without enough USDA inspectors to monitor meat production from start to finish, the public cannot be sure that the meat they eat does not come from cows infected with BSE.

*Robin Kline*

billions a diet with substantial amounts of meat became the goal, a new problem arose: it takes much more out of the environment to make a pound of meat than a pound of vegetable starch or fruits and vegetables. This was not much of a problem when there were fewer humans, and when animals were hunted rather than herded. For some it has become a serious issue that threatens the welfare of our planet.

Plants, of course, as the alternative food source, have their own problems. They are more likely to contain toxins, and they are less calorie dense and less complete nutritionally. As with the minimization of the microbial risks of meat consumption by technological rearing and preparation techniques, the risk of plant toxins can be reduced both by a culture-based selection of appropriate plant products to eat and by the development, through agriculture, of staple plant-based starches that are essentially toxin-free.

## Meat and Vegetarianism

Most people in the Third World eat relatively little meat, mostly because of its cost and rarity. They would eat more if they could. On the other hand, in some religious groups, such as orthodox Hindus, all meat is prohibited. And within some meat-eating cultures, individuals or groups of individuals reject meat as food. This type of vegetarianism has a history that goes back at least to ancient Greece. Historically, this type of elective vegetarianism has been motivated primarily by moral or religious concerns, often having to do with negative reactions to the killing of animals or the psychological effects of consuming animals. Within many developed cultures, vege-

tarians invoke, in addition to moral, religious, or aesthetic concerns, worries about the long-term health effects of eating meat. Some vegetarians can be classified as either health or moral vegetarians, though most long-time vegetarians express a little of both motivations. Interestingly, moral vegetarians are more likely to find meat disgusting than are health vegetarians. When meat becomes disgusting, it is much easier to avoid it.

Vegetarianism seems to be growing in the Western world, impelled by health and moral motivations. For most people who choose this path, it is usually a long development over time, frequently a movement from rejection of a small category of animal products (for example, baby mammals or red meat) through larger and larger spheres of rejection (adding poultry, fish and shellfish, eggs and dairy products, and nonfood animal products). For many, the sequence stops at some point along this trajectory. People also often slide backwards, either abandoning a particular level of rejection for a less stringent set of prohibitions or completely abandoning the vegetarian style.

## Mad Cow Disease

Although in general Americans seemed to be the most concerned group about the diet-health link as the twentieth century ended, the advent of mad cow disease engaged Europeans more than Americans. Mad cow disease (bovine spongiform encephalopathy [BSE]) is quintessentially about meat. Mad cow is doubly animal: it involves not only animal meat—beef—but also feed consumed by cows, animals that are normally vegetarian, that contains animal parts. Studies of risk perception by psychologists indicate that people tend to exaggerate risks when they are catastrophic, hidden, delayed, and not understood. Mad cow disease meets all of these conditions and adds the predisposition to be emotionally involved with foods of an animal nature. It is hard to believe that as much fuss would be made if this were mad broccoli disease. It is also just as likely that “mad broccoli disease,” because it would not originate with diseased animals, would not lead to a delayed, unexpected, hideous, and certain, death.

**MEAT, SALTED.** The food industry incorporates sodium chloride (NaCl) in preservation, processing, and manufacturing operations for vegetables, poultry, fish, seafood, and meat. Although a number of food preservation techniques have been used for many years, including drying, freezing, heating, canning, filtration, enzyme treatment, high-energy irradiation, and chemicals such as organic acids, nitrate, and liquid smoke, salt remains one of the common methods of meat preservation with a long history. Salt is used to preserve meat in its dry form, as a brine, or in solution pumped into tissues (Doyle and Roman, 1982). Researchers still are examining the beneficial functional properties of NaCl in meats and other food commodities (Hajmeer, Marsden, Crozier-Dodson, Basheer, and Higgins, 1999; Psczola, 1997).

## Use of Salt in Meat and Meat Products

Sodium contents of unprocessed meat are about 55 mg/100 g of beef fiber, and 65 mg/100 g of pork fiber (Institute of Food Technologists, 1980). The level is increased when NaCl is added to the meat during processing. Salt has been used by the meat industry as a dry application and in the formulation of fermented, processed (cured or uncured), and restructured meats. Salt added to a meat system serves three main functions: extracting salt-soluble proteins, enhancing flavor, and extending the shelf life (Claus, Jhung-Won, and Flick, 1994).

Originally, in the absence of refrigeration, meat was dry-salted for extended periods of time to preserve it from microbial deterioration. Excessive salting and extended storage increased water loss, and dehydration removed water from the tissues by osmosis, lowering the water activity in the system to conditions unsuitable for microbial growth and leading to cellular plasmolysis, shrinking of cytoplasm away from the cell wall. In addition to dry-salting, NaCl is incorporated in fermented meats such as semi-dry sausage during preparation. Adding NaCl prevents growth of undesirable spoilage or pathogenic microorganisms by favoring the growth of acid-producing, salt-tolerant bacteria, such as lactobacilli and micrococci. Production of acid by these microorganisms gives the meat a desirable tangy flavor and lowers the pH of the system, which adds another safeguard against the growth of undesirable microorganisms.

In processed comminuted meats, for example, bologna, frankfurters, and summer sausage, and non-comminuted meats, for example, ham, bacon, and pastrami, NaCl is one of the basic ingredients, after the meat itself. Other ingredients include water, spices, nonfat dry milk, sweeteners, phosphates, and nitrite. Salt and nitrite are the main ingredients used to cure meats and are applied dry, by immersion, or by injection methods. Salt added to processed meats helps to extract NaCl-soluble proteins, increases the gel strength of the emulsion or batter, enhances the flavor, inhibits or minimizes microbial growth, and enhances antimicrobial activity of other compounds in the system. Salt-soluble proteins coat the fat molecules in the system and provide a stable emulsion, which is important in improving moisture retention and texture of the final product (Claus et al., 1994). Salting prerigor hot-boned meat to be further processed, for example, when making sausage, helps maintain its water-holding capacity (WHC) and fat-emulsifying properties (Hamm, 1981).

Salt, in conjunction with sodium tripolyphosphate, is used for protein extraction in the preparation of restructured meats, which are sectioned and formed non-cured products. Restructuring meats makes it feasible to use lower-grade, less expensive cuts and, similar to the concept of processing meats, restructuring them provides more diversified products that are flavorful, nutritious, affordable, and convenient.

Salt can be encapsulated with partially hydrogenated vegetable oil to prevent excess extraction of salt-soluble proteins during meat processing. This eliminates undesirable changes in meat texture and viscosity. Encapsulated salt used in sausage preparation produces desirable qualities such as high moisture, crumbly and tender texture, and good flavor (Pszczola, 1997). Normally, 2 to 3 percent NaCl is added during the chopping or emulsifying process to help extract the proteins, but this amount may range from as little as 1.5 to 5.0 percent (Claus et al., 1994).

### Advantages, Disadvantages, and Limitations of NaCl

Salt enhances the flavor of meat by suppressing undesirable or unpalatable savors. It extends the shelf life by retarding microbial growth because it exerts both bactericidal and bacteriostatic effects on many microbes found in meat (Marsden, 1980). This might be associated with changes in water activity and ionic strength that render water unavailable to microorganisms (Hajmeer et al., 1999). Other factors include dehydration, the direct effect of chlorine ions, removal of oxygen from the medium, sensitization of microorganisms to carbon dioxide, and interference with the rapid action of proteolytic enzymes (Polymenidis, 1978).

Spoilage and pathogenic bacteria such as *Escherichia coli* O157:H7, *Listeria monocytogenes*, *Salmonella* spp., *Staphylococcus aureus*, *Clostridium botulinum*, and lactic acid bacteria have various tolerances and differ in their responses to salt. Among other factors, these depend on microbial tolerance to NaCl, type and concentration of NaCl, exposure time, pH, and temperature. *Salmonella* spp., *S. aureus*, and *C. botulinum* have the ability to grow in brine solutions with high salt concentrations and at low temperatures (Marsden, 1980). Therefore, using a combination of ingredients and processing methods, such as the curing process, that employ both NaCl and nitrite is important in controlling microbial growth.

Excess use of NaCl has undesirable effects on the flavor, color, and appearance of meat. Application of dry NaCl, for example, can result in an unattractive and darker color of lean (Pearson and Gillett, 1999). As a powerful prooxidant, NaCl has undesirable oxidative effects on meats. Processed frozen products containing salt become rancid and produce unacceptable flavors during extended storage (Claus et al., 1994). Incorporation of other ingredients in the meat system, such as sugar, nitrite, and antioxidants, for example, butylated hydroxyanisole (BHA) helps minimize or control these negative effects by masking adverse flavors, preventing color degradation, and reducing oxidative properties. Salt can have a synergistic effect and enhance the activity of other preservatives such as BHA (Stern, Smoot, and Pierson, 1979). However, impurities in NaCl can reduce its effectiveness in extracting NaCl-soluble proteins because they interfere with the WHC and emulsifying properties

of the meats. Therefore, it is important to use a purified grade of NaCl.

Because of increased concerns regarding high salt intake and its role relative to hypertension, high blood pressure, and potential heart disease, public health authorities recommend reduction in NaCl intake (IFT, 1980). Intake can be reduced by lowering its levels during processing or by substituting potassium chloride (KCl) for part of the NaCl (Pearson and Gillett, 1999). Unfortunately, reduction of NaCl in meat products weakens its preservative capacity and the binding and WHC of the systems. Furthermore, complete replacement of NaCl with KCl is undesirable because of the aftertaste left by KCl. Polyphosphates and other chloride salts also can be used to replace NaCl.

NaCl levels in the diet have been of some concern, and maintaining public health is a priority. Salt use cannot be eliminated completely in the meat industry to reduce health risks because of the important technological functions it performs. It is important to determine the minimum levels of NaCl necessary to maintain its functionality while addressing the health concerns of consumers.

**MEAT, SMOKED.** Smoking is an ancient method of food preservation that is still practiced because it adds an interesting flavor to meat, fish, poultry, and other foods; allows foods such as hams to be stored at room temperature; and slightly dries and preserves some foods, such as sliced salmon, that are eaten raw.

Smoking dates back centuries, especially for fish, which is highly perishable. Archeological evidence suggests that ninth-century residents of Poland smoked large quantities of fish (Shephard, p. 117). In medieval Europe, the religious practice of avoiding meat on certain days created a tremendous demand for fish, and enormous quantities of salmon and herring were salted and smoked in seaside towns before being shipped to the interior. Pork was also a popular meat for smoking since pigs were slaughtered in the fall and their meat could be preserved on the farm to last through the winter. Smoked pork was found in China as well as Europe. In South America, long strips of dried meat are called *charqui*, which has come into English as “jerky” as the name for a snack made from beef or turkey.

Smoking is a preservative because smoke contains chemical compounds that retard the growth of harmful bacteria. More than three hundred components of smoke have been identified. Carbonyl compounds in smoke contribute to the distinctive flavor and aroma of smoked meat, while the carbon dioxide and carbon monoxide help produce the bright red pigment. Phenolic compounds in smoke play a role in protecting fat from oxidizing and turning rancid, which is no doubt a major reason why fatty foods, such as herring or pork, were (and are) so often smoked. The composition of the smoke changes as the temperature of the fire rises, with the best quality smoke produced at a temperature of 650° to 750°F. Control of humidity in the smokehouse is also important since high humidity favors deposition of smoke on the surface of the food and absorption of the flavor. High humidity also assists in the rendering of fat.

Smoking operations fall into two categories: hot-smoking and cold-smoking. In hot-smoking, the temperature in the smoke chamber ranges from 120° to 180°F, which produces a strong smoky flavor. However, the meat is usually only partially cooked and must be finished in a conventional oven. In cold-smoking, the smoke is produced in a firebox but allowed to cool before being passed into the smoking chamber, where the temperature is a mere 70° to 90°F. The food is hardly cooked at all, but long exposure to cool smoke gives the food a mild, smoky flavor and dries it to some extent. Cold-smoking is used largely for foods that will be eaten raw, such as

smoked salmon or smoked fillet of beef. The temperature range from 90° to 120°F is considered too hot for cold-smoking and too cool for hot-smoking. A temperature over 180°F is considered “cooking with smoke” rather than smoking as such; pork barbecue and regional dishes such as Texas beef brisket are in this category. A great variety of foods can be successfully cold-smoked or hot-smoked, ranging from fish to pork, poultry, and beef to wild game.

Many foods are cured before smoking, especially cold-smoking, to draw out the moisture, which would otherwise promote spoilage. The cure is a mixture of salt, sodium nitrate, nitrites, sometimes sugar, spices, and other seasonings, and additives such as phosphates or ascorbates. Nitrate and nitrites contribute to the flavor and coloration of products such as ham. Nitrite and salt inhibit the growth of *Clostridium botulinum*, the bacterium that causes botulism.

A dry cure can be applied by rubbing the meat with the mixture or packing the food in a container of the cure mix and letting it sit for several days or weeks. A wet cure can be applied through a brine of water or other liquid containing the cure ingredients; brine can also be injected into the food in order to impregnate its center and speed up the curing process. Once cured, the food is dried and smoked.

Some items, such as hams, are hung for weeks or months under conditions of controlled temperature and humidity to develop flavor. Humidity is controlled by the addition of steam or water vapor as well as the use of dampers. Air movement is also critical to uniform heating, curing, and flavor in the final product. High air velocities tend to produce more rapid drying and a firm consistency.

Home units for hot-smoking are typically upright cylinders with an electric hot plate, charcoal grate, or gas range at the bottom to produce heat; wood is placed over the heat source to create smoke, and the food is placed on a rack above the wood. A pan of water is often placed in the smoker to catch the drippings from the food so that they do not fall into the heat source and cause flare-ups. The more elaborate units include adjustable baffles and other controls to allow the cook to control the smoke. Double-chamber units for both hot- and cold-smoking are usually horizontal and tend to be rather large and heavy.

Different types of wood are used to produce different flavors in the smoke. Hickory is a great favorite in the eastern United States, while alder is popular in the Pacific Northwest. Maple, oak, and pecan are also used in the United States. In Scotland, peat fires were once used to smoke fish. Beech, oak, and chestnut are the most popular woods in Europe. Commercial operations use sawdust or logs, while most home smokers use wood chips set in a pan on the heating element; the large, dual-chamber home smokers can use small logs. Evergreens

are usually avoided because they contain resins that can produce a sticky smoke and impart a bitter flavor to the food. However, resinous wood is sometimes used at the end of the smoking process to give the outside of the food a protective coating. No matter what fuel is used, a smoldering fire is preferred to an open flame because it produces abundant smoke and avoids very high temperatures.

Smoked salmon, usually sliced very thin, is an elegant dish. It is cold-smoked and eaten raw. Lox (from the Yiddish word for smoked salmon) is usually more heavily cured than other types and is often eaten on a bagel with cream cheese. Kippers are cured and smoked herrings, still very popular in Britain at breakfast, lunch, or tea. The village of Findon in Scotland gave its name to smoked haddock (finnan haddie), which is served hot after being broiled or poached. Halibut, sturgeon, and fish roe (eggs) are also cold-smoked. Eel, trout, and mackerel are hot-smoked and can be eaten without further cooking.

A whole ham is the hind leg of a pig. Many regions in the United States and Europe have particular styles of ham production and preparation. "Country ham" from Virginia, Tennessee, or Kentucky, for example, is heavily cured and smoked for weeks or months over smoldering fires of hickory or apple wood. The resulting ham is so dry and hard that it must be soaked overnight to get rid of some of the salt, and then boiled to soften it. Britain produces the York ham, popular for boiling, the Suffolk ham, cured with spices and honey, and the Bradenham, which is cured with molasses. Prague ham (from Czechoslovakia) is lightly smoked over beechwood coals and is said to be among the sweetest of hams. Many hams are smoked but eaten raw, such as Westphalian ham from Germany. (Prosciutto ham from Parma, Italy, is also raw but is not smoked).

Smoking also gives meat its distinctive reddish color. Sausages are often smoked, as are frankfurters. In the United States, bacon is usually smoked and often cured with sugar to give it a sweet taste.

Chickens, turkey, duck, and geese can be hot-smoked, usually after being cooked, and the resulting meat tastes like ham. Smoked poultry, however, is perishable and must be kept frozen or refrigerated until it is reheated or served cold. Boneless beef roast can be hot-smoked for several hours to the desired temperature and sliced very thin.

Nearly any type of game can be smoked, from squirrel meat to bear and wild boar. Hunters should ensure that game meats are properly handled and cooked to at least 180°F to eliminate the danger of botulism or trichinosis.

**MEDICI, CATHERINE DE'.** Orphaned soon after her birth in Florence, Catherine de' Medici (1519–1589) inherited the wealth and theatrical style of her grandfather, Lorenzo the Magnificent, the most notable of the Florentine family who made the name of Medici synonymous with quattrocento (Italian fifteenth-

Catherine de' Medici (1519–1589), wife of Henry II of France, was better known for her cruelty and political machinations than for culinary sophistication. Nineteenth-century engraving based on an original portrait. © CORBIS (BELLEVUE).

century) art and power. At age fourteen Catherine was sent to France to marry Henry of Orleans (Henry II), who inherited the French throne in 1547 at the death of his father Francis I. Catherine bore ten children. After the death of Henry II in 1559, three of Catherine's sons successively became kings of France, and Catherine served as queen regent.

The thirty-year length of her reign and the horrific religious wars of her time have given Catherine a symbolic identity that stretches historical fact. Popular myth has long named her the Italian queen mother of France's high cuisine, for she is often presumed to have imported new notions of cooking as refined as the other civilized arts reborn in the Italian Renaissance of the fifteenth century. But in fact Catherine's innovations were not culinary but theatrical and were geared to politics rather than to gastronomy.

Regent of a weak government during the conflicts between Catholics and Huguenots that culminated in the St. Bartholomew's Day Massacre of 1572, Catherine used spectacle to create an image of stability and order when reality denied it. In 1564 she displayed the virtual power of monarchy in a grand tour through the countryside with her son Charles IX. Throughout her regency she staged court festivals or masques that used food as the excuse for lavish theatrical happenings, which combined drama with dance, music, sculpture, and the decorative arts. In France she created a new style for royal banqueting that achieved its apotheosis in the court of Louis XIV at Versailles.

**MEDICINE.** Food plays both a causative and curative role in health and disease. Thus, its role in medicine may be as a risk factor for, protector against, or treatment of an illness. While too much food or exposure to certain foods can reduce someone's health, too little food or inadequate amounts of certain foods can be equally damaging. In the years before modern transportation, packaging, and refrigeration, medicine was primarily concerned with food deficiencies and food spoilage. The focus of medicine was on the identification of critical components of food and common pathogens and on the prevention of nutritional deficiencies and foodborne infections. The role of food in medicine has changed as food production, preservation, and preparation techniques have progressed. Today far more people in de-

veloped countries such as the United States suffer from excessive food consumption than from food deficiencies. In addition, certain components of food have been found to have therapeutic or protective properties when administered in levels greater than generally considered necessary. For instance, large quantities of vitamin A are used to treat acne, therapeutic quantities of vitamin E may be protective against heart disease, and extra fiber appears to reduce the risk of colon cancer. However, the problems of malnutrition or inadequate food intake and foodborne illness have not been eliminated. Undernutrition continues to plague developing nations, while the prevention and treatment of foodborne illness is a concern for all nations.

#### The Basics of Food and Health

Food is fundamental to support life. People get energy, water, and all of the building blocks for growth and proper bodily functioning from the foods they eat and the liquids they drink. The components of food necessary to life are termed "nutrients" and the study of the role of food in health is called nutrition. The goal of medicine is to ensure health, and because adequate nutrition is necessary to accomplish this, nutrition is a crucial component of medicine. Nutritional science combines food science and medical science. Nutrients include protein, fat, carbohydrates, fiber, thirteen vitamins, seventeen minerals, and more substances that are still being identified. The majority of nutrients essential to health are found in a variety of different foods. No one food is absolutely essential to support life. People with access to adequate amounts of food get all of the nutrients they need by eating a varied diet complete with fruits, vegetables, meat or meat alternatives, dairy foods, and grains. However, some people are not able to or do not choose to eat the full variety of foods available. These people may require special foods or supplements to meet their nutritional needs.

#### The Study of Food in Medicine

All branches of medicine, from pediatrics to geriatrics and from internal medicine to surgery, study food and its role in health and disease. Nutritional scientists in government, industry, and academia are constantly seeking to understand the role food plays in illness and well-being. Meanwhile health-care practitioners treat patients with nutritional plans and food supplements. Registered dietitians are health-care specialists who integrate food into medical treatment—this is referred to as medical nutrition therapy.

#### The Role of Food in Maintaining Health

Although the presence of adequate nutrition does not ensure health, it is a significant contributor. The energy contributed by the protein, carbohydrates, and fat in food provides the fuel for every element of body functioning from breathing to thinking to fighting disease to running

marathons. Adequate energy intake is crucial to promote proper growth and development as well as to maintain healthy functioning once one is fully grown. Food also provides the materials necessary to build healthy bone, muscle, skin, hair, etc. For example, bone is a complex matrix of calcium, phosphorus, and collagen fibers. A person's bone strength is directly related to their nutrient intake such that inadequate calcium intake is one of the primary reasons for bone disease such as osteoporosis. Nutrients are also necessary to support proper chemical and neurological functioning. For example, fat insulates nerve fibers such that they can conduct electrical signals along the length of the body. Meanwhile, those electrical signals are generated via channeling ions such as sodium, potassium, and calcium into and out of the nerve cells. Finally, the neurotransmitters released from the nerve cells are made from amino acids contributed largely from proteins in the diet. Thus, thinking and feeling are intricately connected to food.

### Food for Those Who Can't Feed Themselves

Food is generally eaten, or drunk, and swallowed. However, many people cannot obtain adequate nutritional levels by conventional ways of ingesting food. In the past, these people would suffer and die from malnutrition. Modern nutritional medicine offers people several alternatives to conventional chewing and swallowing of food so that those who cannot do so will not die. Liquid solutions have been manufactured by pharmaceutical companies that are easier to digest than solid food and provide 100 percent of nutritional needs. People who can drink but not eat rely on these formulas just as babies who cannot breast feed rely on baby formula to meet their nutritional needs. People who cannot consume anything orally are fed via a tube inserted into the stomach or intestines. Finally, those whose gastrointestinal tracts cannot absorb even liquids are fed intravenously with solutions that provide 100 percent of human nutritional needs.

### Examples of Food as a Cause of Disease

Food allergies and intolerances are common medical reasons for eliminating specific foods from one's diet. An *allergy* is an immune response to proteins in food that the body identifies as foreign. The most common food allergies include those to peanuts, tree nuts, shellfish, milk, soy, corn, wheat, and eggs. Most allergies appear in childhood and require complete elimination of the offending food if the symptoms are to be eradicated. Childhood food allergies may persist for a lifetime or may resolve a few years after getting rid of the offending food. Symptoms of allergies may include rashes and other skin irritations, gastrointestinal inflammation and bleeding, and respiratory distress, which may even involve arrest of breathing.

Food intolerances are not allergies but rather uncomfortable reactions to food that are not generally considered life threatening. One well-known example is

lactose intolerance. Lactose is the carbohydrate in milk and other dairy products. The body requires a specific enzyme if lactose is to be absorbed. As people age their bodies may make less of the enzyme necessary to break down lactose and as a result they may experience gastrointestinal distress, including such symptoms as gas or diarrhea, when they consume milk products containing lactose. Most people with lactose intolerance can tolerate dairy products if they accompany their meal with a lactase enzyme pill or if they consume dairy products pretreated with lactase enzyme. Thus, food technology allows people with intolerances to tolerate the offending foods but avoidance is the only option for people with food allergies.

In countries such as the United States where food is abundant, some of the greatest medical risks result from overeating rather than insufficient eating. For example, an excess intake of energy in the form of food leads to an increased risk of obesity. Obesity increases one's risk of cardiovascular disease, cancer, diabetes, and obstructive pulmonary disease—among the most common and most deadly diseases today. Medical practitioners have tried to determine how much food is adequate to support healthy living. People who consume too much food and become obese may seek medical treatment to lose weight and treat diseases resulting from obesity. Treatments may include nutritional therapy, exercise programs, drug therapy, or surgery. *Foodborne illness* results from eating contaminated food. Foodborne illness can be caused by parasites, bacteria, viruses, toxins, or other pathogens that are harmful to humans. Food is not the direct cause but rather the carrier of the problematic agent. The effects of foodborne illness can range from flulike symptoms to death depending on the type of pathogen and the amount of exposure. Foodborne illnesses are generally prevented by appropriate growing, harvesting, packaging, preparation, cooking, and storage of food. However, many countries lack the technology and resources necessary to accomplish this. Thus, assuring food safety continues to be an area of international concern.

### Food as a Treatment

Food is not only necessary to sustain health but it can also help ill people regain health. Although the common advice to "feed a fever" may sound like folklore it is actually based in scientific evidence. A rise in body temperature is required in order to fight disease. People with a fever also require extra energy if they are to have adequate energy to maintain their strength while they battle illness. Likewise, the immune system uses a wide range of nutrients to combat intruders. All infectious diseases result in increased need for nutrition to strengthen the immune system as if fights against invading viruses or bacteria. People who suffer from diseases such as cancer, cystic fibrosis, and acquired immunodeficiency syndrome (AIDS) generally require extraordinarily large amounts of nutrients to battle their disease. Likewise, young chil-

dren who are ill require extra food to ensure that they have adequate nutrition to ensure normal growth and development. Food is crucial in combating both minor and major illnesses.

Many specific nutrients defend against disease. Calcium, a mineral found mainly in dairy products, is critical in the promotion of bone health and protection against osteoporosis. Fluoride, now added as a supplement to most water supplies, is crucial to tooth development. Iron is most commonly found in meats and protects against anemia. Folic acid prevents neural tube defects such as spina bifida in developing fetuses and has recently been found to protect against cardiovascular disease. In fact, almost every vitamin and mineral is known to be critical to one or more life processes. Nutritional specialists and medical practitioners are constantly studying the role each nutrient plays in protecting the body and investigating further possible cures.

**MEDIEVAL BANQUETS.** Banquets during the European Middle Ages were often given on such important ecclesiastical feast days as New Year and Pentecost. But the greatest ones for which we have records were given for weddings and the coronation of kings or installation of bishops. There were also banquets for funerals, the coming of age (or knighting) of a son, or such lesser occasions as a harvest, the feast day of the patron

saint of the local parish guild, various civic occasions, or even a tournament. Who was invited depended on the circumstances; wedding guests were apt to be family and close friends, as today, but many people of quite humble status would be included in festivities at a manor house.

This is not to say that banquets were frequent: they were very special occasions. Of the twenty-seven menus given in the fourteenth-century *Menagier de Paris*, a work compiled by an elderly Parisian for his young wife, only three are banquet menus: two for weddings and one for a civic event (Brereton and Ferrier, *Le Menagier de Paris*, pp. 175–190). The fifteenth-century English manor house of Dame Alice de Bryene, for which we have complete records of meals served over a period of a year (28 September 1412–28 September 1413), had only one major banquet that year, serving dinner to 160 people on New Year's Day. But it also provided fairly lavish meals to many of those involved in gathering the harvest in August, with several dinners for from forty to sixty guests, about twice the number usually present at Dame Alice's table.

#### Menus

The food served was quite different in quantity, and in some respects nature, from everyday meals, which for most people were apt to start with (or, for the poor, consist of) vegetable pottages (soups or stews). For a banquet, vegetables, if any—in England, they rarely appear on feast menus—were vastly outnumbered by a parade of roasts or fish of all kinds, and more elaborate dishes. Even the pottages were usually ones considered as special treats, such as frumenty (a wheat or barley pottage) with venison, or a *blancmange* of chicken or fish in spiced almond milk, usually also containing rice.

What is most striking to the modern eye about the menus for important banquets is the number of dishes served. An extreme example is the banquet celebrating George Neville's installation as Archbishop of York in 1465, which had a first course containing seventeen dishes, a second with twenty, and a third with twenty-three—not counting the “subtleties,” discussed below. Three was the normal number of courses for the high (head) table at an English banquet, two for lesser guests. At the coronation feast of Richard III, there were three courses for high table, two for the lords and ladies, and one for commoners—who included the Lord Mayor of London!

Usually the dishes given to those not at high table were a selection of those in the three-course menu, including the most basic dishes. A feature of the (fictional) thirteenth-century banquet of Walter of Bibbesworth (Hieatt and Butler, *Curye on Inglyshe*, pp. 2–3) is that there was enough venison and frumenty for the “whole household,” clearly suggesting that not everyone got a taste of all the goodies that followed.

Manuscript 279 in the British Library's Harleian collection gives two-course menus for “the lower part of the

Depictions of medieval banquets are not common in secular art, but in religious paintings, biblical stories are often shown as medieval events. In this case, the Banquet of Herod, during which Salome serves up the head of John the Baptist, appears as a medieval banquet complete with table linens and customary serving vessels. From the Convent of Saint John the Baptist. © SANDRO VANNINI/CORBIS.

hall” for the banquets celebrating the installation of John Stafford, Bishop of Wells, and the wedding of the Earl of Devonshire (Austin, pp. 63–64). In the first case, the two-course menu is a selection of seventeen of the forty-seven dishes on the three-course menu, but the wedding banquet has less overlap, substituting several dishes not found on the three-course menu. These are not all humbler dishes: they include Caudel Ferry, a dish of sweetened wine thickened with eggs, resembling a modern *zabaglione*, and doucetys, custard tarts.

### Distribution of Dishes

Those lower in rank not only got fewer courses but also were served smaller portions. Only the host and any exceptionally high-ranking guest got an individual serving; other high-ranking guests shared dishes (messes), usually two to a mess. If there were lower-ranking guests, as there would have been at a manor house, they were more apt to dine three or four to a mess. Sometimes those of higher rank were so served, to judge by a German banquet scene

showing a number of crowned ladies at the side tables being served four to a mess.

This does not mean that those at high table ate all they were offered. The lord (or lady) of the house was expected to give some of the choice dishes to others. The thirteenth-century “household rules” for the Countess of Lincoln, attributed to Bishop Robert Grosseteste, advise that her “dish be so refilled and heaped up, especially with the delicacies, that you may courteously give from your dish to right and left to all at high table and to whom else it pleases you.” The fifteenth-century Latin poem *Modus Cenandi* tells us empty plates are to be brought to the host so that he may distribute delicacies to others, and many recipes tell us to allow a whole chicken for a lord but only a quarter for commoners (“The Way of Dining,” Furnivall, pp. 231–257).

If the Countess of Lincoln was to offer food from her dish to others at high table, clearly even those honored guests were not served everything on the menu. Just

how many they had to choose from in each course probably varied according to the wealth and generosity of the host. The fourteenth-century poem *Sir Gawain and the Green Knight* describes lavishness that is highly unlikely in real life when it states that the members of King Arthur's court at a New Year's feast had so many dishes that it was hard to find room on the table for them: "Every two had twelve dishes / Good beer and bright wine both" (translation of lines 128–129).

### Order of Service

Generally there was soup or other pottage to start with, followed by meats (on a meat day), with the more commonplace boiled or roasted meat and fowl first; on a fish day, there would be salt fish. More "delicate" items, such as roasted wild birds and fresh fish, came next, along with other dishes, then sweet or richer foods including tarts and fritters. This order is already apparent in that banquet described by Walter of Bibbesworth, although there the pottages follow rather than precede substantial meats. But some fifteenth-century menus for grand occasions were so expanded that each course might run the gamut from soup to fritters.

The basic order is spelled out in *Modus Cenandi*, which calls for pottage to be followed by meat of large animals and fowls, then smaller ones, and finally "better dishes" (*fercula dant meliora*). This "natural rule" is also claimed in the *Liber Cure Cocorum*—that for a feast featuring fowl, the larger ones come first, then "bakyn mete" (mainly pies), with more dainty foods at the end. A similar order is found in continental banquet menus, with a few differences.

French banquet menus varied in the number of courses, but the basic model seems to consist of four courses. The first course was much like an English first course, except that it excluded roasts. Roasts, with some accompaniments, came in the second course, and more elaborate dishes (*entremets*) in the third. Any or all of these courses might consist of only one or two dishes, as is the case with one of the *Menagier's* menus for wedding feasts. As in England, the French last course (*dessert*) usually included sweet dishes and/or fruit, although it might also contain meat or fish dishes we would not consider dessert today.

Italian banquets ran to more courses: eight, ten, and sometimes twenty or more courses, generally with two or more dishes in each. Sometimes they began with pasta dishes, but otherwise the order was much like the French: soups and meats in sauces preceded roasts. German banquets also ran to a good many courses, but most of them consisted of a single dish.

### Setting and Protocol of the Banquet

The menu order, however, does not give the complete order of the banquet. The first thing given to all diners was water and a towel for washing hands, usually before

they were seated at the table. They were seated strictly according to rank at tables which, for a large banquet, were arranged in a U-shape. The host and especially honored guests sat at the head (high) table, and the others at the side tables. The nearer a guest was placed to the host, the greater the honor. The principal salt cellar, often a very elaborate affair, was placed at the host's right hand: hence the saying that others sat "below the salt." Salt for general use was distributed in piles on pieces of bread that served as individual salt cellars.

On the table, guests would find bread, and often a knife, a spoon, and a napkin, but not a fork: fingers or pieces of bread were used to pick up food not eaten with a spoon. "Trenchers" of coarse bread were cut and placed in front of each diner to receive pieces of meat or fish. Wine and/or ale would soon be poured, but before the meal was served, grace was said. Food was brought from the (often distant) kitchen; the German banquet scene referred to above shows a servant bringing a pile of covered dishes, much like those used in restaurants today to keep food warm. Roasts were carved and served in the hall.

French banquets usually started with an aperitif, or *assiette de table* (as against the *première assiette*, first course). *Grenache*, a fairly sweet wine (compare modern French aperitifs), seems to have been usual, with such accompaniments as fresh fruits, butter, salad, or small meat or fish pastries. While English banquet menus do not mention aperitifs, John Russell's *Boke of Nurture* (Furnivall, *The Babees Book*, p. 122) advises serving soft fruits before dinner, and they would seem to be the same fruits recommended for the aperitif course in France.

It is thus possible that aperitifs may have sometimes preceded the first course in England. The English menus often omit mention of how the meal ended, although we know the custom was the same as in France: a sweetened, spiced wine was usually served with wafers, fruit and cheese being an alternative way to end the banquet. After grace and the final handwashing, the table was cleared (or removed) and more wine and candied spices followed, at least for the higher-ranking diners.

### Entertainment

Anyone who has seen medieval pictures of banqueting scenes will have noticed musicians almost invariably present, blowing fanfares to herald the beginning of a course or playing to entertain the diners while they eat. Other entertainers might include minstrels, jugglers, mummers, or players putting on a pageant or interlude, a form of theatrical entertainment referred to in *Sir Gawain and the Green Knight*. This poem is also one of many sources of evidence that the guests themselves did a lot of singing and dancing. Since the banqueting in the poem takes place in the Christmas season, much of the singing and dancing consists of carols. But a major source of entertainment at a medieval banquet was apt to be culinary in nature, at least in part. This was what was known in England as a subtlety, usually a creation of sugar, marzipan,

or pastry depicting one or more birds, beasts, or people, brought out at the end of every course. At the coronation feast of Henry V, the subtlety at the end of the first course was a (confectionery?) swan surrounded by cygnets, all of whom carried messages in their bills that were lines of verse. But that was not enough. Twenty-four more swans followed, each one carrying the last line of the poem. Some subtleties were considerably simpler, including foods decorated with a motto or appropriate symbol, such as a coat of arms.

In France, subtleties were known as *entremets*, indicating their placement between courses. But the situation is complicated by the fact that *entremets* were originally just interesting dishes brought out between courses: the *Menagier* considers any elaborate dish to be in this category, including jellies and frumenty. This explains why frumenty with venison, which invariably appears at or near the beginning of the first course in England, occurs in the third or fourth course in France.

Still, the French also prepared elaborate *entremets* that are certainly in the category of subtleties. One of the manuscripts of the *Viandier de Taillevent* contains a number of these, some of which are edible: for example, the “helmeted cocks” for which roasted chickens are mounted on roasted piglets, with paper helmets and lances, probably wooden but covered with foil. But the *Viandier*’s “painted *entremets*” are strictly decorations, made of wood and other inedible materials, depicting such subjects as a knight in a swan boat, sailing on a cloth sea.

**MEDITERRANEAN DIET.** The Mediterranean diet is defined variously. It sometimes refers simply to the dietary patterns and social mores surrounding eating in the countries bordering the Mediterranean Sea. In nutritional parlance the meaning is somewhat more confined. It applies to the traditional diet of European countries on the Mediterranean as characterized by foods and by patterns of nutrient intake.

Italy, Greece, France, and Spain are particularly associated with the diet because they were involved in the several ecological studies of dietary patterns, lifestyles, and coronary artery heart disease in the 1950s and 1960s led by Ancel Keys of the University of Minnesota (Keys, 1970, 1995; Keys et al., 1954). These landmark studies associated the relatively high dietary fat intake in those countries with a much lower prevalence of coronary artery disease than in the United States or northern Europe. Since dietary fat was thought to be the major culprit in coronary artery disease, this seemed remarkable at the time. Later discoveries linked saturated fat and cholesterol rather than total fat to heart disease risk. Olive oil, high in monounsaturated fat, and fish, high in polyunsaturated fat, which constituted the majority of the fat in the Mediterranean diet, were associated with lower risk. Other aspects of the food and nutrient profiles and lifestyles (for example, more physical activity, less smoking, etc.) may have contributed to low disease risk as well.

#### Reasons for Interest

Originally, interest in the Mediterranean diet was based on that association with decreased risk of coronary artery disease. The traditional Mediterranean diet included liberal amounts of fruits, vegetables, legumes, grains, and wine; high amounts of monounsaturated fats; moderate consumption of alcohol; liberal amounts of fish; and low amounts of meat and milk products. The diet was accompanied by a lifestyle that involved a good deal of obligatory physical activity, no smoking, and a relaxed at-

titude toward life. The actual diets were usually moderate in energy for physical activities. They were also relatively low in saturated fats and sugars and relatively high in most of the fat- and water-soluble nutrients and phytochemicals.

In the late twentieth century nutritional scientists attempted to examine whether or not the Mediterranean diet is associated with decreased risks of other diseases. Where traditional diets conforming to the Mediterranean pattern are eaten, health benefits seem to be present. In addition, the increased American interest in fine dining, ethnic cuisine, and food habits contributed to the popularity of the Mediterranean diet.

### Evolution of the Mediterranean Diet Concept

Keys popularized the Mediterranean diet in the early 1970s, and other nutritionists, culinary experts, and commodity groups subsequently advocated it. In the early 1990s, Oldways, a group dedicated to preserving traditional eating patterns, joined members of the Harvard School of Public Health in conducting a series of conferences and other activities to popularize the Mediterranean pattern. This group published a healthy-eating Mediterranean pyramid based on the dietary traditions of the region.

### Mediterranean Diet Pyramid

The Mediterranean diet pyramid is available at the website. W. C. Willett, and colleagues described it at length in "Mediterranean Diet Pyramid," published in the *American Journal of Clinical Nutrition* in 1995. The pyramid puts bread, other grain products, and potatoes at the base. The second tier is vegetables, including beans, other legumes, and nuts, and fruits. Third is a shallow tier for olive oil, and next is a cheese and yogurt tier. All of these foods should be consumed daily.

Near the top of the pyramid are small blocks for foods consumed a few times a week, including fish, poultry, eggs, and sweets. At the peak of the pyramid are foods consumed only a few times a month, including red meats, fats, oils, and sweets. The pyramid is accompanied by a wineglass to indicate "wine in moderation" and a running stick figure with the headline "regular physical activity" (Wilson, 1998).

### Acceptable Alternative or Dietary Imperative?

Is consumption of a Mediterranean diet mandatory for good health? The notion of a single Mediterranean cuisine has been criticized on the grounds that no single such diet exists and that to contend one does promotes stereotypes and fails to account for the dynamic nature of dietary changes. Also, diets in the Mediterranean region and elsewhere in Europe change rapidly and no longer reflect those of yesteryear. Many healthful dietary patterns are associated with diets designed to reduce chronic disease risks. It is not necessary to consume diets similar to those traditionally eaten in the Mediter-

anean to stay healthy, but the Mediterranean diet is one alternative that provides an appropriate and healthful nutrient pattern.

Does the inclusion of Mediterranean-type foods make contemporary American diets healthier? This depends on a number of factors, chiefly how they are used. While decreased risk is associated with traditional Mediterranean diets, the patterns in these countries have changed a great deal since the early 1950s. They may not always provide all of the health advantages their traditional counterparts did, especially if food is eaten in excess. The specific health benefits of individual foods rather than the entire Mediterranean pattern are also unclear. Although most of the traditional foods are delicious and nutritious, other foods with similar nutrient compositions would seem to be equally effective. Therefore simply adding one or more "Mediterranean" foods to American diets does not necessarily provide positive health effects. The overall pattern in moderation has been linked to positive health outcomes.

During the late twentieth century, awareness of the considerable culinary and aesthetic advantages of the Mediterranean diet grew. Many staples of traditional Mediterranean diets have become popular and are widely available in the United States and other Western countries.

The plant-based Mediterranean diets of the early and mid-twentieth century were environmentally sound and responsible in the locales in which they flourished. Whether they are exportable and feasible on a large scale in other climates in non-Mediterranean countries is a matter of debate.

Traditional food habits typical of countries bordering the Mediterranean Sea in the mid-1950s have health and nutritional advantages. Guides for eating in the Mediterranean manner are readily available, but following their advice is not mandatory for good health.

**MELANESIA.** See **Pacific Ocean Societies**.

**MENU.** See **Places of Consumption; Restaurants**.

**MESOAMERICA.** See **Central America; Mexico; Mexico and Central America, Pre-Columbian; South America**.

**MESOPOTAMIA, ANCIENT.** Cuneiform clay tablets from ancient Mesopotamia, the region between the Euphrates and Tigris Rivers (mostly present-day Iraq), preserve a few kitchen recipes dating from the eighteenth to the seventeenth centuries B.C.E. Except for these texts, the oldest recipes known, our information about food supplies and their processing is indirect: on the one hand, dictionarylike lists of foodstuffs and, on the other, administrative texts recording the acquisition and expenditures of raw staples and kitchen supplies. A few proverbs and literary passages occasionally give additional details. Although an enormous number of names of edible plants, animals, condiments, and the like is known, in too many cases their exact identification is not possible. In contrast with Egypt, food remains of ancient Mesopotamia, other than bones and seeds, are extremely rare (Ellison et al.). In Mesopotamia, cooking was considered to mark, alongside clothing, the beginning of civilization. To quote an ancient Sumerian poem ("The Debate between the Ewe and the Barley," Alster and Vanstiphout) describing prehistoric times:

The men of those remote days  
did not have bread to eat,  
did not have clothes to wear.  
People went around with naked limbs,  
ate grass with their mouths, like sheep,  
drank water from the gullies.

The onset of historical time is metonymically described as "when bread was eaten in the shrines of the land, when the ovens of the light were burning" ("Gilgamesh and Enkidu," George).

### Lexical Information

Extensive word lists covering the botany, zoology, and material culture of southern Mesopotamia are a typical element of cuneiform literature. Among the oldest intelligible tablets (c. 2900 B.C.E.) there are lists of cereal and dry meat products, vegetables and alliaceous plants, fish, and birds. These lists were expanded through the centuries, culminating after the fourteenth century B.C.E. in long classical lists that were in use until the second century B.C.E. In an encyclopedic compilation of twenty-four tablets, of an average length of three hundred lines each, there is one dedicated to domestic animals (XIIIth tablet), one to wild ones (XIV), one to meat cuts (XV), one to plants (XVII), one to birds and fish (XVIII), and two to foods and drink in general (XXIII–XXIV). In detail, Tablet XXIII has three long sections:

1. soups
2. beer and brewery products
3. flours and bread

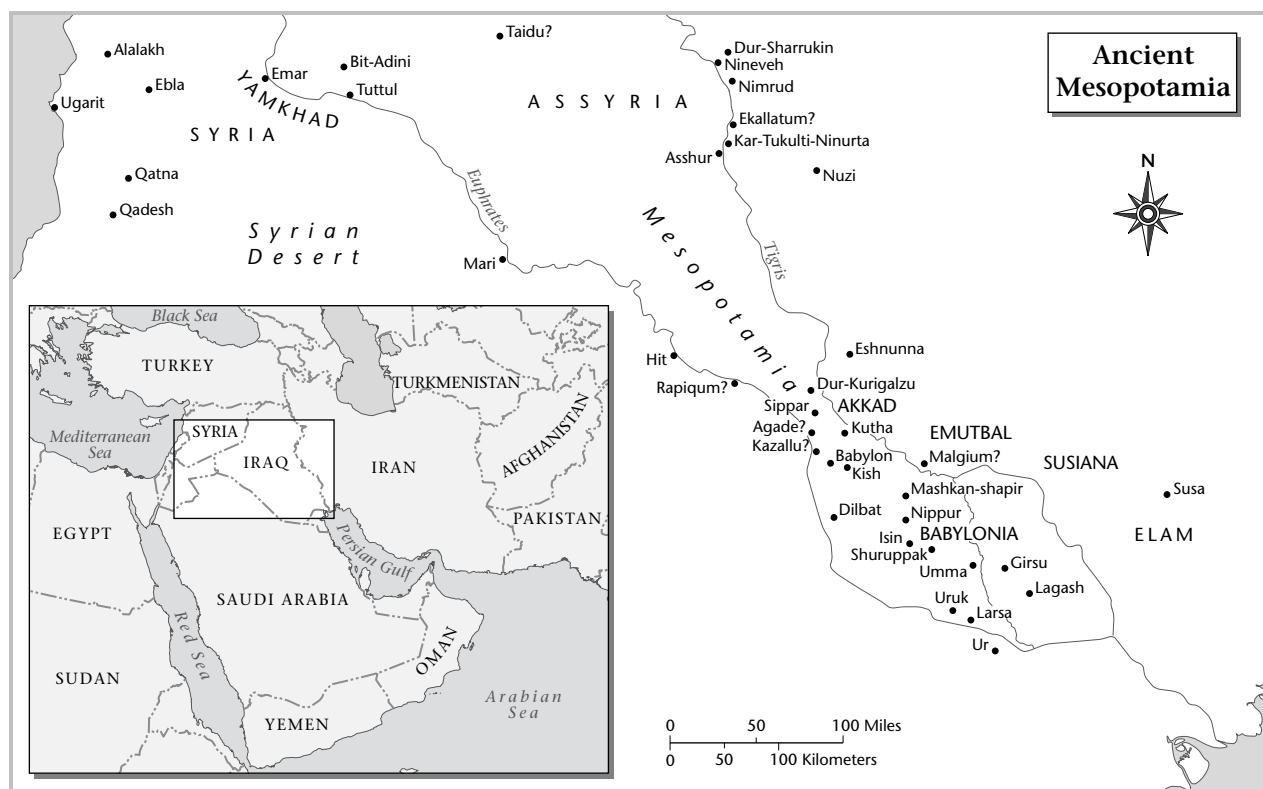

Tablet XXIV is more varied:

1. syrups and honey (12 entries)
2. oils and fats (53)
3. spices (11, also treated elsewhere in other tablets)
4. seeds (12, also treated elsewhere)
5. dairy products (34)
6. pulses (8)
7. emmer and wheat (10)
8. barley (67)
9. straws (10)
10. fruits: figs, raisins, pomegranates (10), dates (at least 38).
11. salt and condiments (12)
12. melons and cucumbers (8)

These lists are Sumero-Akkadian bilinguals (Mesopotamian culture was bilingual from its earliest days). Sumerian is an isolated language, but Akkadian is Semitic, a sister language of Hebrew and Arabic, and thus it is helpful in the identification of some food names, although too many uncertainties still remain. For instance, the names of the two condiments more often mentioned, after salt, in the texts of the end of the third millennium, are *gazi* and *zabili*. Neither of them is unambiguously identified.

### Accounting

A meticulous and detailed accounting system is another typical feature of Mesopotamian civilization. Adminis-

trative tablets, found by the tens of thousands, give a general idea of the circulation of goods, of supplies, their origin, and their destination. A substantial number of these tablets deal with alimentation. Thus, for instance, an archive of c. 2400 B.C.E. from the town of Girsu gives us detailed information about the teams of fishermen, their catch classified by species, the amounts regularly provided to the governor's palace, and so on. By their nature, these accounts give better information about the tables of the upper classes, and very little about the diet of the working population. What is known about the latter comes from payment sheets that show that a workman would get about six liters of barley for a hard day's work. Women and children were given less.

### Cereal Products

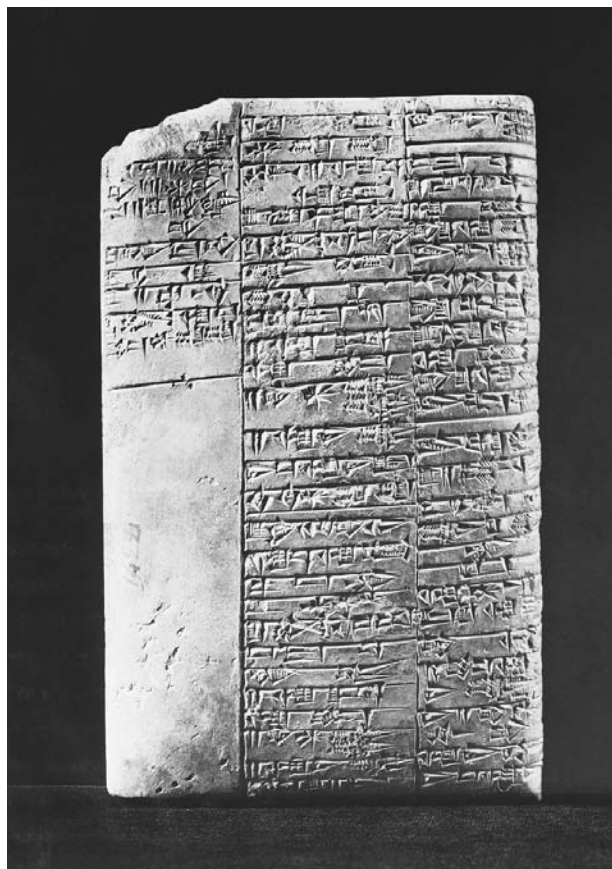

Locally grown cereals, mostly barley and relatively small amounts of emmer wheat and wheat, constituted the nutritional base in ancient Mesopotamia. Cereals were consumed in the form of bread, soups, and beer.

**Bread.** Bread (Sumerian, *ninda*; Akkadian, *akalu*) must have been made, at least in some cases, from leavened dough. There are no direct descriptions, but allusions to its bulky size and to leaving the dough overnight to rest seem to be indications of fermentation. One may assume, however, that in most cases the bread was made from unleavened dough shaped into flat, round loaves, similar to the present-day Near Eastern *khubuz*. This bread was baked in a peculiar, ubiquitous type of oven called an

*öürin* (Sumerian) or *tinûru* (Akkadian). It was a clay implement of cylindrical shape, tapering to a conical form in its upper part and with a side opening at its base. The whole was between 3 and 4 feet high. Once the oven was sufficiently heated, the flat, unleavened loaves were plastered to the side for baking. Salaries of the workers were often paid in bread. Roasted barley was sold in the streets and at the marketplace.

**Alcoholic drinks.** The Mesopotamian brewing process is relatively well known: the fermentation of a mixture of malt and barley bread, with the addition of sugar in the form of dates, produced different types of beer (Sumerian, *kaö*; Akkadian, *öikaru*) consumed by drinking with a straw from a communal jar. This beer had a short shelf life due to a certain instability caused, among other factors, by the absence of hops. Only in later periods, after the seventh century B.C.E., are there indications of the addition of an element, perhaps cuscutea, with a function similar to hops. Lists of supplies to brewers give the relative amounts of ingredients for various types of beer, but the absence of any indications about the processing does not allow any evaluation of the final product. The same ingredients can result in products of quite different taste and aspect, depending on the processing. A fermented beverage made of dates was also known. Chemical residues have identified some jars as wine containers in the late Uruk period, c. 3500 B.C.E. (Badler et al.). Wine, nevertheless, is mentioned rarely, and although there were some vineyards in the south, in the Lagash area and

This 4,000-year-old Sumerian tablet in the collection of the museum of the University of Pennsylvania is inscribed with one of the oldest known medical remedies. The ingredients are ground to a powder, then served to the patient in beer—a primitive form of medical dietetics. Other tablets in the same collection contain culinary recipes. © BETTMANN/CORBIS.

in the eastern hills toward Iran at the end of the third millennium, the climatic conditions were in general unfavorable for growing vines. The conditions were better in the north, in the hilly regions of Assyria. Some wine may have been imported from the northwest in Syria where the conditions were better. Consumption of alcoholic drinks, beer above all, seems to have been substantial. The rations given to the royal couriers and travelers consist always of bread and beer. There are lists of supplies for festive occasions, and drinking parties (*kaö-dé-a*, literally, “the pouring of beer”) are mentioned. These parties—one could perhaps call them “receptions”—were celebrated for religious, social, or political reasons such as the visit of foreign ambassadors, often with the presence of the king and his court.

### Animal Products

Meat, from sheep, goats, and cattle, seems to have been consumed regularly by the upper classes, only occasionally by the rest (Limet). Salted, dried strips of meat are

mentioned already in the oldest texts. The use of meat must have been more extensive than sparse mentions in texts seem to suggest. The consumption of pork, initially frequent, seems to have declined after the beginning of the second millennium. The extreme south of Mesopotamia was an immense estuary with lagoons and marshes where fowl and fish were present in huge quantities. Fish is better documented for the older periods up to 3000 B.C.E. Whether the subsequent decline in fish consumption is real, for reasons of taste or availability, or apparent, due to administrative changes, is hard to say. Semitic populations seem to have held fish in low esteem. Fats for cooking were predominantly of animal origin (lard, tallow, suet); vegetable oils, presumably from sesame, were reserved mostly for cosmetic, ritual, and technical (tanning hides, cloth finishing, etc.) uses. For example, the total production of vegetable oil in the Girsu province in 2047 B.C.E. was some 14,445 liters, but none of it was earmarked for cooking. Dairy products, including clarified butter and various types of cheeses, were very important, but there are no indications about the consumption of fresh milk by adults; its preservation must have been severely limited by climatic conditions. Dairy fats were the only ones used in the confection of pastries. Hunting (enormous flocks of gazelles roamed the desert until a few centuries ago) is often described in royal commemorative texts but has left no trace in bureaucratic records and must have been a sport (lions and boars being a favorite prey) rather than a means to procure subsistence. As for more exotic foods, an Assyrian relief shows a servant carrying locusts impaled on long sticks.

### Vegetables and Fruits

If close to a hundred names of green vegetables, as well as their parts and varieties, are known (from Tablet XVII of the compilation listed above), their use is poorly documented, due probably to their perishability, which made them unsuitable to be recorded by the bureaucratic administration. An exception are the alliaceous plants (onions, garlic, leeks), which are less perishable, and evidently much esteemed and consumed in large amounts by all levels of the population. There are detailed accounts of the production of onion beds. Lettuce was particularly appreciated, judging from its mention in literary texts. The names of many spices are known but, as usual, their identification is extremely difficult. The fruits more frequently mentioned are apples, figs, and pomegranates; the first two were often dried, and a ring of dried apples from the royal tombs of Ur (c. 2700 B.C.E.) has been exceptionally preserved (Ellison et al.).

The date palm occupied a place apart. It grew easily in extensive gardens on the southern plain and the tree production was the object of careful bookkeeping. Besides the fruit, which was eaten dried and was a source of a fermented drink, most parts of the palm were useful for making ropes, baskets, and ceiling beams. Date syrup seems to have been the main sweetener; beekeeping is

## RECIPES FROM ANCIENT MESOPOTAMIA

Genuine cooking recipes, written about 1700 B.C.E., have been preserved on three cuneiform tablets in the collections of Yale University and are available in a professional edition and commentary by Jean Bottéro. One of them gives instructions to prepare “twenty-one meat soups and four vegetable ones” in a rather concise style. The other two are much more detailed, but the text is less well preserved. They are almost completely devoted to the preparation of fowl dishes. It is quite possible that these cuneiform tablets are survivors of a large collection of culinary works. The style of cooking described represents probably the activities of the cooks of some royal court, perhaps from the later part of the Larsa Dynasty (ended 1763 B.C.E.) since it appears from older texts that birds were a favorite dish at the queen’s table. The interpretation of these recipes is hampered by the usual uncertainties in the identification of the spices and other ingredients, as well as in the meaning of some highly technical terms. Follow the translations of the recipes (adapted from Bottéro, 1995) for a simple soup and for a complicated dish of wild pigeon (additional comments in square brackets):

1. To prepare goat’s kid soup. Singe the head, legs, and tail [the parts of the animal to be used], the meat will be ready. Prepare the water, add fat, onions, *samidu* [a type of flour preparation, or a spice], leeks, and garlic bound with blood, crushed *kisimmu* [a type of cheese or coagulated milk], and an adequate amount of wild onion [*Alilium desertorum*].

The addition of blood (of what animal is not specified, the kid’s presumably here) as a binding and flavoring agent is frequent in these recipes. Amounts and cooking times are left to the experience of the cook.

2. To prepare wild pigeons (*amursânu*) in broth. Slaughter the wild pigeon and, after soaking it in hot water, pluck it. Once plucked, wash it with cold water and skin the neck, leaving attached to the body the skin with its meat. Cut out the ribs. Open the underbelly and remove the gizzard. Wash and soak the bird in cold water. Open and peel the membrane from the gizzard. Cut open

and chop the intestines. To cook in broth, first put in a kettle the gizzard, intestines, and head, as well as a piece of mutton [fat], and cook it. Remove from the fire. Wash well [the bird] with cold water and wipe carefully. Sprinkle with salt and assemble all the ingredients. Prepare the broth, adding a piece of fat from which the gristle has been removed, some vinegar, *samidu* flour, leek and garlic, mashed with onion, and if needed add some water. Let simmer. When it is cooked, pound and mash together leek, garlic, *andahöu* [a kind of onion], and *kisimmu* to add to the dish [follows a damaged passage in which apparently the pigeon is disjointed and the legs are covered with dough]. When everything is cooked, remove the meat from the fire, and before the broth cools, serve it accompanied with garlic, greens, and vinegar. Carve and serve. The broth can be consumed later by itself.

The kind of wild pigeon of this recipe is known to have been regularly supplied centuries earlier to the royal kitchens for its consumption by the queen and ladies of the court. These recipes also include instructions to make a sort of bread to accompany the fowl dishes. It was made of sifted *sasku* flour, a sort of semolina, mixed with milk and condimented with *siqqu*, a salty paste made from fish and crustaceans, akin to the garum of the Romans. It was kneaded “being careful that it remains pliant,” and condimented with leek and garlic. Part was formed to line the bottom of the serving plate, and part to make small loaves (*sebetu*). It was left to rise, and then baked on the bread oven already described.

These are at present the oldest known recipes. Nothing has survived from the following centuries, except for a short isolated recipe written in a small tablet probably from the fifth or fourth centuries B.C.E. It describes the preparation of a spiced liquid in which to cook meat:

The right amount of roasted *nuhurtu*, roasted [seeds of] mustard(?), roasted cuscutea, and roasted cumin. Boil slowly with [dried] cucumber in 6 quarts of water until it is reduced to 1 quart. Filter it. Kill the animal [to be cooked] and throw it [in the liquid].

This is a general-purpose cooking liquid for meat. The recipe illustrates once more the problems raised by the difficulties in identifying the ingredients.

not documented until very late times, and whenever the texts mention “honey,” it must be generally assumed that it refers to date syrup. There are isolated allusions to mushrooms, but their consumption seems to have been considered a barbaric custom: the stereotyped ethnic description of the Bedouin nomads has them digging for truffles. Present-day Bedouins are still very fond of the

white truffle (*Tarfezia leonis*) and of a smaller red-brown one, growing in the desert after rain from February to April.

### Religious and Social Uses of Food

The sacrifice of cattle and smaller animals was an essential part of many religious rites, generally accompanied

Bas-relief on the ancient Assyrian throne of Shalmaneser III depicting offering bearers carrying various items of food. Courtesy of the Iraq Museum, Baghdad. © GIANNI DAGLI ORTI/CORBIS.

by bread, pastry, and beer libations. The only food taboo mentioned is the abstinence from fish and leeks by some type of priests (and by some evil spirits). Banquets and dining halls, but with very vague information about the dishes served in them, are mentioned in the mythological and historical texts. Meat dishes (lamb mostly, rarely beef) and beer are invariably included in the menu.

In 879 B.C.E., the Assyrian king Assurnasirapli II boasts, on an inscription on a stele (Grayson, pp. 288–293), of having given a gigantic banquet, on the occasion of the inauguration of his new palace, for no fewer than 69,574 guests, from workers to dignitaries, local and foreign. The supplies for this banquet give an idea of the requirements of the Assyrian gourmet, leaving aside the question of the historical precision of the round numbers: 1,000 oxen, 1,000 calves, 14,000 sheep, 1,000 lambs, 500 deers, 500 gazelles, 1,000 large birds, 500 geese, 500 cranes, 1,000 mesukku-birds, 1,000 qaribu-birds, 10,000 pigeons, 10,000 turtle doves, 10,000 smaller birds, 10,000 fish, 10,000 akbiru (a small rodent), 10,000 eggs, 10,000 containers of beer, 10,000 goatskins of wine, 10,000 jars of a hot condiment, 1,000 boxes of fresh vegetables, and large quantities of honey, pistachios, roasted grain, pomegranates, dates, cheeses, olives, and all kinds of spices. These are the highlights of a list thirty-six lines long on the stele.

### Kitchens and Utensils

Professional cooks (Sumerian, *mubaldim*; Akkadian, *nubatimmu*), assigned to palaces, temples, and other institutions, are known from remote antiquity. The common name for the kitchen was “the cooks’ house,” or “the cooks’ room.” The most frequent type of bread oven, often encountered in the ruins, has already been described

above. The names of larger ovens, called *udun* and *kir*, are also known, but their physical features are difficult to ascertain. Although remains of large ovens and fireplaces of various types have been found in archeological excavations, there is no comprehensive study so far of their characteristics. Cooking and serving utensils, from large kettles to soup bowls, are known by name, but it is not easy to assign these names to the various types of clay and metal containers recovered by the archaeologists.

### Recipes

There was a tradition according to which the kitchen recipes came from Enki, the god of wisdom and knowledge. Thus, one reads in a literary text: “King (?)ulgi will have a banquet in his pleasant palace after large beautiful dates mixed with raisins, butter from the holy sheepfold, and the sweetest (date) honey have been worked together, and the sweets have been mixed with fine flour, according to the good instructions of god Enki” (unpublished translation). This passage describes the preparation of a very traditional type of cake (Sumerian, *ninda-ì-dé-a*; Akkadian, *mirsu*). The administrative “shopping lists” give at times the ingredients for a given dish or confection. From them one can infer that this cake required, for instance, the following proportion of ingredients: fine flour: three cups; clarified butter: one-fourth cup; dates: one cup. Small amounts of cheese or raisins were occasionally added. This of course is not really a recipe; it tells what, but not how.

**METABOLIC IMPRINTING AND PROGRAMMING.** It has long been recognized that environmental influences during early development have profound and long-lasting effects on humans and other animals. Metabolic imprinting describes a subset of such effects, comprising subtle but persistent responses to prenatal and early postnatal nutrition. This article will describe how the term "metabolic imprinting" was conceptualized and will provide some examples of putative metabolic imprinting phenomena to illustrate the important roles they may play in human health.

### Background

A growing body of human epidemiologic data suggests that the quality and quantity of nutrients available during prenatal and early postnatal development can affect susceptibility to various adult-onset chronic diseases, including cardiovascular disease, type-II diabetes, and hypertension. Some of the earliest indications of such relationships were gleaned from ecological data showing a regional correlation between infant mortality and mortality from cardiovascular disease several decades later. These data led researchers to postulate that a poor environment that causes high infant mortality could also impair the development of surviving infants, increasing their susceptibility to cardiovascular disease in adulthood.

David Barker's group in the United Kingdom bolstered the ecological data by collecting retrospective data on individuals. By linking obstetric records from the early 1900s with mortality records from several decades later, his group found that individual birth weight was related inversely to adult cardiovascular disease mortality. In numerous populations in industrialized countries, similar relations were later found between birth weight and morbidity and mortality associated with cardiovascular disease, coronary heart disease, and type-II diabetes. Viewing birth weight as a proxy for the quality of the prenatal environment, these relations were interpreted to indicate that prenatal factors (such as maternal nutrition) could "program" the development of adult chronic disease. Extensive epidemiologic research investigating this so-called "fetal origins" hypothesis is underway. How-

ever, the inherent weaknesses of human epidemiologic research in this field, including the long period of follow-up from exposure to outcome and inability to accurately adjust for various potential confounding variables, limit our ability to draw causal inferences from epidemiologic relations alone.

### The Concept of Metabolic Imprinting

It remains unknown whether developmental responses to fetal and early postnatal nutrition are major determinants of chronic disease susceptibility in humans. Understanding the biological mechanisms underlying such phenomena in appropriate animal models should help to gauge their potential importance to human health. The term "metabolic imprinting" was proposed to provide a framework for the investigation of such biological mechanisms. Metabolic imprinting encompasses adaptive responses to specific nutritional conditions early in life that are characterized by 1) susceptibility limited to a critical ontogenic period early in development (the critical window), 2) a persistent effect lasting into adulthood, 3) a specific and measurable outcome, and 4) a dose-response relationship between exposure and outcome (Waterland and Garza, 1999). "Programming" has been used as a more general term to describe effects that occur when "an early stimulus or insult, operating at a critical or sensitive period, results in a permanent or long-term change in the structure or function of the organism" (Lucas, 1991; p. 39). However, imprinting, first used to describe the setting of animal attachment behavior based on early experience, more effectively conveys the important characteristics of the phenomena under consideration. As Konrad Lorenz noted, ethological imprinting occurs only during "a quite definite period" in the animal's life and the imprinted behavior "cannot be 'forgotten'" (Lorenz, pp. 126 and 127). The remainder of this section will discuss the most salient features of metabolic imprinting.

Adaptive responses are those that contribute to survivability of the organism. Limiting the scope of metabolic imprinting to adaptive responses excludes persistent effects of severe nutritional deficiencies or exposure to toxic levels of specific nutrients during critical stages of development. For example, it is well established that neural tube defects can be caused by maternal folate deficiency during early embryonic development. Also, fetal exposure to pharmacological levels of vitamin A can cause teratogenesis. Clearly, both of these examples represent persistent effects of early nutrition, but neither is adaptive. It may seem illogical to propose that adaptive responses putatively characterized as metabolic imprinting could contribute to adult chronic disease susceptibility. However, adaptive responses in early development are not necessarily beneficial throughout an individual's life. A metabolic response that increases prenatal or early postnatal survivability in one environment may prove detrimental to the individual in a different environment or at a later ontogenic stage.

The “critical window” criterion in the definition of metabolic imprinting limits consideration to effects resulting from nutritional perturbation of developmental pathways. Mammalian development occurs in stages. At each stage, specific processes must be completed in a limited time frame to enable progression to the next stage. A given nutritional stimulus may have diverse effects, depending on the developmental processes underway during the stage at which the stimulus is applied. Therefore, each specific metabolic imprinting phenomenon should have a finite critical window.

To illustrate, the fertilized mammalian egg proceeds through a series of reductive cell divisions (cleavage) to the formation of the three germ layers (gastrulation), to the establishment of organ rudiments (organogenesis), to the stage of histogenesis, when cellular differentiation results in the formation of specialized cell types and, lastly, to metabolic differentiation, during which the specialized functions of the different cell types proceed toward functional maturation. Organogenesis requires inductive interactions between adjacent germ layers. Hence, during organogenesis, localized concentrations of diverse nutrients or their metabolites could alter organ structural development by interacting with these signaling systems. As another example, the wave of rapid cell proliferation that follows cellular differentiation in various organs puts a high demand on the nutrients necessary for the synthesis of cellular components. Transient deficiencies (or excesses) of these food-derived precursors during limited periods of rapid cell proliferation could result in permanent alterations in cell number and, hence, metabolic activity.

### **Examples of Putative Metabolic Imprinting Phenomena**

It should be emphasized that metabolic imprinting remains a theoretical construct intended to provide a framework for investigations into the biological mechanisms linking early nutrition and adult chronic disease susceptibility. Research is underway to identify candidate phenomena that satisfy the criteria of metabolic imprinting. This discussion therefore focuses on candidate phenomena that appear most consistent with metabolic imprinting.

Retrospective studies linking birth weight to adult chronic disease outcomes represent by far the most numerous class of epidemiologic data in support of metabolic imprinting. Studies of many different populations have found that individual birth weight is related to adult risk of coronary heart disease, hypertension, type-II diabetes, stroke, overweight, and other disorders. In most cases, there is a simple inverse correlation, with adult disease risk increasing as birth weight decreases. Some adult outcomes, such as type-II diabetes, appear to follow a “U-shaped” relation with birth weight, with adult risk increasing at very low and very high birth weights.

Proponents of the fetal origins hypothesis conclude that these examples demonstrate that nutritional status

during critical periods of fetal life influences the development of diverse organ systems, leading to effects on adult chronic disease risk. As discussed above, however, there are many limitations to the interpretation of such long-term retrospective epidemiologic studies. Moreover, there are several reasons that birth weight is not an ideal proxy for fetal nutritional status. For example, maternal nutritional status during pregnancy is just one of many factors that determine infant birth weight. Also, an individual’s genetic makeup could influence both fetal growth and adult susceptibility to a specific disease, leading to an association between birth weight and adult chronic disease that is not mediated by fetal nutritional environment. Conversely, it is likely that fetal nutrition can affect metabolic development without affecting birth weight. Hence, a misplaced focus on birth weight as the major early-life predictor of adult chronic disease susceptibility could result in a gross underestimation of the importance of metabolic imprinting to human health.

For these reasons, studies of human populations with documented exposure to extreme nutritional conditions in early life are an important source of support for the metabolic imprinting hypothesis. The best characterized of such populations comprises individuals exposed perinatally to starvation during the Dutch famine of 1944–1945. In 1976 Gian-Paolo Ravelli and co-workers published an analysis of Dutch military draft induction records of 300,000 young men and found that, compared to those born in non-famine-stricken control areas, men who were exposed to famine conditions at some time during the first six months of fetal development experienced an 80 percent higher prevalence of overweight. In contrast, those exposed to famine during the last trimester of gestation and/or the first five postnatal months experienced a 40 percent lower prevalence of overweight. Perinatal famine exposure was later related to adult glucose tolerance in several hundred individuals from the Dutch famine cohort. During standardized glucose tolerance tests, plasma glucose concentrations were higher in adults who had been exposed prenatally to famine than in individuals born before the famine. Because the timing, severity, and geographical extent of nutritional deprivation caused by the Dutch famine were well documented, these studies are not weakened by the methodological issues inherent to observational studies predicated on birth weight.

In the only large-scale experimental trial designed to investigate metabolic imprinting-like phenomena in humans, Alan Lucas and co-workers randomized preterm infants to receive standard infant formula, a special preterm formula, or banked breast milk during the first month of postnatal life. At the start of the trial, none of the feeding alternatives were clearly superior for preterm infants, allowing ethical randomization of early diet in this cohort of several hundred individuals. In this ongoing study, long-term follow-up has already shown that subtle differences in early postnatal diet affect cognitive development and bone mineralization in childhood. Conversely,

childhood growth, body composition, and blood pressure were not associated with the early dietary exposure.

Controlled experimental investigations in animal models have demonstrated the biological plausibility of metabolic imprinting. Such studies have confirmed that subtle variation in prenatal and also early postnatal nutrition can affect adult outcomes including glucose-stimulated insulin secretion, blood pressure, body weight, organ structure, and lipid metabolism. Guided by the framework of metabolic imprinting, future animal studies of candidate phenomena should identify the tissues responsible for their effect persistence and characterize their critical windows to generate testable hypotheses about the effects of early nutrition on specific developmental processes.

### Significance

Subtle nutritional perturbation of developmental pathways may have an important impact on human health. The immediate challenge for researchers in this field is to elucidate the specific mechanisms by which nutrition influences biological development in appropriate animal models. Doing so will suggest specific areas of focus for future research into the biological links between early nutrition and adult metabolism in humans. Clearly, the potential importance of gaining this information is great, especially in populations that continue to be at high risk for marginal nutritional status in early life.

**METAPHOR, FOOD AS.** "The essence of metaphor is understanding and experiencing one kind of thing in terms of another" (Lakoff and Johnson, p. 5). Many aspects of social and cultural life are talked about and experienced in terms of food. This kind of comparison occurs easily because of the systematic organization of food and food habits within each culture. Through language and through daily practices, food is ordered in terms of the categorization of foods, the organization of food production and consumption, and the linguistic expressions about food and eating. Cultural systems of food and food habits form conceptual frameworks that are metaphorical in nature. In other words, food, as anthropologist Claude Lévi-Strauss tells us, is good to think with.

Food can serve as a metaphor for family, religion, sex, gender, social position, and group identity, among other things. These principal metaphors appear across cultures, but are organized locally as different peoples speak of different foods and equate them with specific elements of their lives. The following overview of food as metaphor provides explanations of the different metaphorical constructs with a variety of specific local examples.

### Food as a Metaphor for Religion

Food is a powerful metaphor for sacrifice, order, obedience, self-discipline, purity, generosity, and other key values in religious and ritual life around the world. Special rules and practices concerning dietary standards and ceremonial behavior distinguish and make concrete complex values and belief systems.

For example, Jewish food practices revolve around kashruth, the dietary laws outlined in the Old Testament books of Deuteronomy and Leviticus. Kashruth prohibits the consumption of pork, shellfish, reptiles, and amphibians and calls for the strict separation of dairy and meat foods. Anthropologist Mary Douglas interprets this regulation of food as part of a larger process of ordering the natural world according to social and moral precepts. By systematizing everyday experience into categories of clean and unclean, kashruth provides a practical foundation for understanding theological classifications and the proper relationship to God. The value of order is reiterated in the Passover seder, a ritual meal that metaphorically reenacts the Jews' flight from slavery in Egypt.

In the Hindu belief system, food is a metaphor for body, mind, and spirit. Daily and ceremonial rituals of food-giving demonstrate the values of generosity and selfless service. Fasting and dietary self-control are metaphors for mental clarity and religious authority, while prohibited or improperly prepared foods are believed to cause spiritual unrest and poor health. Anthropologist R. S. Khare notes that Hindu holy people are highly sensitive to individual foods and must strictly monitor their diets in order to maintain physical, mental, and spiritual balance.

## Food as a Metaphor for Sex and Gender

Ideas about “Man the Hunter” and “Woman the Gatherer” permeate understandings of gender in contemporary Western societies. The man who “brings home the bacon” is a competent provider for his family; “he’s a meat and potatoes man” connotes a hearty appetite and robust character. These and other sayings connect masculine qualities such as virility and strength with the provisioning and consumption of meat. After all, “real men don’t eat quiche.”

Among the indigenous peoples of Papua New Guinea, food production, gender relations, and human reproduction are intertwined in a metaphorical cycle of energy exchange. Men are credited with cultivating staple crops to meet the nutritional needs of the community, while women’s task is to raise children, supplying the next generation of “manpower.” In this context, men’s agricultural practices are understood in terms of feminine procreative abilities. Watering the crops is likened to breast-feeding, and men who are actively cultivating their gardens are subject to the same food taboos as pregnant and nursing women (Meigs).

Food is not only used to communicate ideas about gender roles; it can also express overtly sexual qualities. Food acts as a visual metaphor for sex in many art forms. It can convey voluptuousness and sensuality (a lingering shot of ripe fruit), temptation and the arousal of desire (oysters as aphrodisiacs), and consummation and fulfillment (sharing food as an exchange of bodily juices). Food is also used in linguistic metaphors when food items are compared to body parts in scatological references to sexual activity, and, more generally, as terminology for sexual “appetite,” “hunger,” and pleasure is common also for food and eating.

## Food as Metaphor for Family

Food can be used metaphorically to talk about and enact various elements of social interaction and organization, one of which is the family. Cross-culturally, the family represents many things. It is a basic form of social organization, an economic unit, and a structure for social and cultural reproduction.

In some societies, growing certain crops, distributing food, and preparing food are the responsibility of one side or another of the family—of the woman’s side of the family in some societies (Richards), of the man’s side in others (Weiner). Food production and preparation represent and enact the extended family networks that structure kinship-based models of social organization.

In many contemporary Western societies, the nuclear family is often the basic economic unit, in which money for food provisioning and then food preparation are centered. The way people organize their food and meal-related activities also helps define the roles of individuals in the household. These roles may be gendered or age-dependent. The pleasure of eating and serving food becomes a metaphor for the structure and emotion

of family relationships (Ochs et al.). A family discussion about food preparation tasks, or about who eats what and why, may also actually be a more concrete means of addressing issues of household division of labor, family power structures, and family dynamics.

When family commensality takes place around a table, or around a cooking hearth, the place for the meal is a metaphor for family solidarity. Indeed, in many cultures the hearth is thought of as the center of the home—home in the sense of family space.

The affective and sensory aspects of food, as well as shared experiences of foods, can help cement the family unit via associations of certain foods with specific people and events. For example, the smell of a roast turkey may evoke fond memories of a time when family comes together. In this way, tasting and reminiscing about food items metaphorically bring up family members and family bonds without explicitly mentioning them. Recipes and food-related stories also provide links between generations and help ensure the transmission and reproduction of cultural practices and family, ethnic, local, and national identities.

## Food as Metaphor for Social Hierarchy

Regulation of food and food habits is a persistent metaphor for social stratification. Such varied systems as class, caste, and status can all be thought of in terms of food. For example, food as class positioning arises in discussions of people and their consumption patterns. In the consumer societies of North America and Europe, eating caviar and foie gras and drinking expensive Champagne are seen as consuming luxury goods and are associated with the wealth of the upper classes. In certain Andean countries, the kind of starch eaten most frequently marks overlapping boundaries of class and ethnicity, with potatoes consumed by poor, rural farmers of Native American descent and white flour and bread consumed mainly by the more wealthy urbanites of European descent (Weismantel).

## Food as Group Identity: Local and National Identities

The idea of food as metaphor for the eater’s identity comes across clearly in popular parlance. For example, the expression “You are what you eat” goes beyond the physical realities of the human digestive process and nutrient absorption. It compares one’s existence to one’s eating habits and can extend to others’ existences—and, hence, to people’s perceptions of others and their ways of labeling others.

**National identity.** People’s nationalities are sometimes spoken of in terms of the foods they eat. Not always positive, food stereotyping can be pejorative, as in the case of the French being called “frogs” by the British and the British being referred to as “roastbeefs” by the French. While food metaphors can deconstruct identities, they also construct them.

Anthropologist Emiko Ohnuki-Tierney analyzes Japan's elaborate mythic histories, rituals, and public debates about rice as attempts to define the essence of a distinctive national identity. As a central metaphor in Japanese culture, rice is surrounded by a complex system of beliefs: each grain of rice is a living being with its own soul; "the Deity of the Rice Paddies" is a benevolent, peaceful figure embedded in the agrarian landscape; the soul of the deity is manifested in the perfection of rice grains; eating rice is a religious act as the consumer ingests the spiritual energy of rice and the rice god. Rice is also a focus of artistic and literary production: writers extol the beauty of rice, and painters idealize agrarian society. In daily life, a meal is not complete without rice, women are judged by their ability to cook it, and family cohesiveness is expressed by serving rice from a communal bowl. Efforts to restrict the importation of "foreign" rice reveal the extent to which Japanese notions of self and national identity are intertwined with this staple food.

**Local identity.** Preserving local food habits both practically and metaphorically promotes the survival of a variety of local and ethnic groups because community members experience and transmit their local identity in terms of food-related experiences. For example, in some minority cultures of the southeastern United States, such as the Gullah of South Carolina and Georgia, community-centered storytelling, recipe-sharing, cooking instruction, everyday food preparation techniques, and festival rituals maintain cultural identity by preserving the specificities of rice-based foodways (Beoku-Betts).

Sometimes local identities are constructed or maintained in the face of more encompassing identities. In this sense, food is a metaphor not only for the specific local identity in question, but also for political and cultural resistance. Some French farmers promote local, artisanally produced foods against the pressures of globalization in the food industry. For example, José Bové has made headlines in the United States and in Europe by leading demonstrations against international food companies, such as McDonald's, and by promoting his locally produced Roquefort cheese outside the doors of international trade meetings.

## Conclusion

Not just figures of speech, metaphors express relationships of ideas, using the terms of one conceptual system to achieve understanding of another. As frameworks for thinking about the world, metaphors are shaped by their cultural context. Yet food-based metaphors crop up around the globe. Food and food systems are "good to think," often serving as a metaphor for complex issues such as family, religion, sex and gender, social position, and group identity.

**MEXICO.** The Mexicans form a mestizo nation, born of the intermarriage of Spaniards and Native Americans, and their foods reflect this mixed heritage. Before the conquest of Mexico by the Spanish, the indigenous people created a sophisticated cuisine based on the staple grain maize (corn), which they cooked in a multitude of fashions, from everyday tortillas (griddle cakes) to festive tamales (dumplings). The conquistadors, hoping to establish a New Spain in the Americas, transplanted their familiar foods, particularly wheat bread, which was the foundation of the Mediterranean diet and the only grain accepted by the Catholic Church for the Holy Eucharist. Royal officials attempted to segregate Hispanic and native societies throughout the colonial period (1521–1821), but widespread race mixing occurred nevertheless. Ethnicity became a function more of culture than color, and eating corn or wheat, like speaking Spanish or Nahuatl, denoted a person's status. While the staple grains

remained largely separate, culinary blending took place among the condiments, as indigenous cooks incorporated European meats into their moles (chili pepper stews) while Hispanics adopted native chilies and beans. The rejection of European doctrines of racial superiority came only after the revolution of 1910, when Mexicans accepted *mestizaje* as the national identity, and the combination of wheat bread and corn tortillas as the national cuisine.

In addition to class and ethnic divisions, Mexican cuisine contains tremendous regional variation. Perhaps the simplest classification consists of three complementary pairs: the mestizo foods of the central plateau and the indigenous center of Oaxaca in the south; foods of the frontiers of the Maya in the southeast and of Spanish settlement in the north; and the distinctive foods of the Gulf and Pacific coasts. Although Spanish influence tended to prevail in the north while the Indians better retained their culture farther south, no simple formula can capture the disparate topographies, climates, and settlement patterns that combined to produce these rich regional cuisines.

This diversity notwithstanding, a number of characteristics, common throughout Mexico, compose an identifiable national cuisine. As the original site of the chili pepper's domestication, Mexico has both the greatest botanical wealth of chilies, with some ninety different varieties, and the highest per capita consumption, since vir-

tually no Mexican considers a meal complete without some kind of peppers. The structure of the meal, with a succession of individual courses, unifies the Mexican dinner table and distinguishes it from the combination plates found in restaurants north of the Rio Grande, which jumble together the rice—properly eaten before the main course—with the beans that should follow. A common calendar also exists, combining religious feasts such as Christmas and Easter, secular holidays like Independence Day, and community and family celebrations of saints' days and weddings, each with their own traditional foods. The Mexican diet has been changing recently as a result of globalization and the spread of both junk food and haute cuisine, but these influences represent merely the latest in a long series of culinary encounters.

### Cosmic Cuisine

José Vasconcelos helped define the Mexican national identity in *La raza cósmica* (*The Cosmic Race*, published in 1927), which rejected Social Darwinist views about the problems of race mixture and instead proclaimed mestizos to be the highest form of human evolution. This new nationalist ideology, called *indigenismo*, brought about the revalorization of Mexico's native heritage, including the indigenous cuisine based on corn. But embracing the pre-Hispanic past did not imply a rejection of Spanish contributions to Mexico's development, especially wheat

bread and European livestock. Many other ethnic groups also contributed to Mexico's "fusion" cuisine, from African slaves and clandestine Jews in the colonial period, to European and Chinese immigrants in the nineteenth century and Lebanese and North Americans in the twentieth century.

One of the most fundamental cultural clashes between Native Americans and Spaniards in the colonial period revolved around the staple grains, corn and wheat. Maize not only provided the nutritional basis of pre-Hispanic civilizations, accounting for as much as 80 percent of the caloric intake of common people, it also served as the basis for religion and identity. Spanish missionaries therefore sought to substitute the European wheat as part of their work of extirpating the idolatry associated with indigenous corn gods, but their evangelical mission was undermined by economics as well as taste. Corn made an ideal subsistence crop, growing well in all manner of ecological niches from the tropical forests of Yucatán to the mountains of the central plateau. Wheat, by contrast, was here a fragile plant, susceptible to disease, requiring lavish irrigation, and offering comparatively low yields even under the most favorable circumstances. As a result, corn remained the staple crop of the rural masses in both native and mestizo communities, while wheat was grown as a market crop for wealthy Hispanic city dwellers. The price differential between wheat bread and corn tortillas persists to the present day, as do many of the stereotypes formed during the colonial period. Affluent Mexicans invariably keep wheat bread on the table, even when serving dishes such as mole, which is more properly eaten with corn tortillas.

The greatest European influence on Mexican cuisine came from the introduction of livestock. Before the Spanish arrived, the native inhabitants consumed a basically vegetarian diet incorporating only two domesticated animals, turkeys and dogs. The deaths of millions of Native Americans due to Old World diseases such as smallpox and measles, against which they had no natural immunities, opened up large amounts of formerly cultivated land for grazing. With no competitors, the cattle, sheep, goats, and pigs, and chickens brought by the Spanish reproduced at a fantastic rate, although their numbers soon declined through overgrazing. During the colonial period, the elite retained the Spanish preference for mutton, and only the poor consumed beef. Over the course of the nineteenth century, with the adoption of French fashions, the consumption of beef surpassed that of mutton. Mexicans also developed an elaborate art of *tocinería* (sausage and other pork products), and pork fat became the invariable cooking medium, despite European preferences for olive oil and butter. Culinary blending occurred through the incorporation of chili peppers into Spanish dishes such as chorizos (sausages) and *adobos* (marinades). Although Native Americans initially rejected the taste of lard, they eventually learned to add it to tamales and beans, improving their taste and texture.

The complexity of culinary blending can best be seen in the debate over the origins of the national dish, *mole poblano*, an elaborate festival food of turkey served in a deep brown sauce of chili peppers, diverse spices, and a small amount of chocolate. Anthropologist Margaret Park Redfield, who studied the foods of a native community near Mexico City in the 1920s, at the height of the *indigenista* movement, described mole as an essentially pre-Hispanic legacy of chili cookery. Fifty years later, disillusioned by the Mexican government's refusal to respect indigenous rights, anthropologist Judith Friedlander examined a neighboring village and reached the opposite conclusion: that mole, with its numerous Asian spices, had been imposed by Spanish missionaries. A third interpretation, based on popular legend rather than scholarly analysis, attributed the complexity of *mole poblano* to the Baroque artistry of the city of Puebla, where colonial nuns supposedly combined Old World spices with New World chilies to symbolize the mestizo "cosmic race." The lack of pre-Hispanic and colonial culinary literature makes it impossible to resolve the question definitively, but all three versions probably contain an element of truth.

Successive waves of immigrants, despite their relatively small numbers, have added significantly to the culinary blending of Spanish and Native American. Jews fleeing the Spanish Inquisition came to the colonies, par-

ticularly the northern province (now state) of Nuevo León, where their distinctive dish, *cabrito* (roasted kid), remains a regional specialty. African slaves meanwhile diffused their skills with rice agriculture throughout the Caribbean basin, including coastal Mexico. In the eighteenth century Italians began arriving from Naples, then part of the Spanish Bourbon empire. They had already established noodle factories in Mexico City by the 1790s, not long after the industry was founded in southern Italy. After independence in 1821, British miners brought with them a taste for meat pies, called *pastes*, around Pachuca (Hidalgo), site of the Real del Monte silver mine. German immigrants opened up breweries, and by the twentieth century their beers had supplanted the native beverage pulque, the fermented juice of the maguey (century [agave]) plant. French foods were the most fashionable among the nineteenth-century Mexican elite; nevertheless, all of these immigrant foods underwent a process of nationalization, so that Parisians today would scarcely recognize many of the dishes served under French names in Mexico City.

More recent immigrants have also left their mark on Mexican cooking, although none more so than the fast-food invasion from the United States. Large numbers of Chinese settled in northwestern Mexico in the late nineteenth century after the United States passed exclusion laws forbidding them entry. Then in the 1920s Lebanese immigrants began arriving, particularly in Puebla and Yucatán, and the gyro became the inspiration for *tacos al pastor* (shepherd's tacos). By the 1940s industrial processed foods from the United States had acquired enormous popularity among the rising middle class. Aunt Jemima pancakes became a favorite breakfast food, while Coke and Pepsi battled for the soft drink market. Moreover, these imports had to compete with domestic products such as Pan Bimbo, a Mexican clone of Wonder Bread. The spread of junk foods to even the most remote indigenous communities by the 1970s further complicated Mexico's diverse gastronomic geography.

### Many Mexicos

Of the many culinary regions in Mexico, none exhibit the mestizo blending to a greater extent than the central highlands. The city of Puebla, legendary home of *mole poblano*, illustrates Iberian cooking techniques used on native ingredients through the production of *camotes* (candied sweet potatoes). Toluca is known for superb chorizo sausages combining pork with chili peppers. In the state of Hidalgo, shepherds pit-barbecue lamb wrapped in the leaves of the maguey to make a local specialty called *mixiotes*. Nahua Indians in the states of Mexico and Morelos cook *nopales* (cactus paddles), squash blossoms, and *cuitlacoche* (corn fungus) in quesadillas (corn pastries fried in pork fat). All of these different foods, and indeed the culinary traditions of the entire country, can be found in cosmopolitan Mexico City, with its countless markets, restaurants, and street vendors.

**Oaxacan cuisine.** In contrast to this cultural blending, indigenous communities such as the Zapotecs and Mixtecs in the southern state of Oaxaca have preserved their traditional foods. Unlike the complex blend of spices in *mole poblano*, the Oaxacan *mole verde* (green mole) derives its pristine taste from a few simple chilies and herbs, most notably the anise-flavored *hoja santa*. Oaxacan cooks wrap tamales in banana leaves instead of the corn husks common farther north, and they have raised tortilla making to a high art with the large, soft *blanditas* and *tlayudas* as well as the crisp *totopos*. The tiny grasshoppers known as *chapulines*, another local specialty, are flavored with smoky *chipotle* chilies and eaten in tacos with guacamole.

**The Gulf Coast.** Cooks along the Gulf Coast prepare seafood in both Mediterranean and pre-Hispanic styles. The snapper Veracruz (*buachinango a la veracruzana*) served in the eponymous port city contains olives, olive oil, tomato, capers, and only the mildest green peppers. Farther up the coast, at Tampico, one can sample the fiery hot crab soup called *chilpachole*. In the northeastern tropical forest of the Huasteca, ethnic groups such as the Totonacs make more than forty different types of tamales, including the legendary meter-long *zacahuil*, which can feed an entire village. Other seafood specialties of the region include baked pompano, *robalo al mojo de ajo* (snook cooked in garlic), and various seafood soups, cocktails, and *escabeches* (pickled seafood).

**The Pacific Coast.** The most typical food of Pacific Coast states is not from the sea at all, but rather *pozole*, a hominy stew made with pork. This dish comes in a number of different varieties, red in Guadalajara, green and white to the south in Guerrero, and with tripe in the northern state of Sonora. A common street food, eaten late at night, *pozole* is served with chili powder, oregano, chopped onion, sliced radishes, shredded lettuce, and limes for squeezing. In port cities such as Acapulco, the citric acid of lime juice is used to "cook" fresh seafood into *ceviche*. The Purépecha Indians of Michoacán prepare a variety of distinctive tamales, most notably the triangular *corundas* and fresh-corn *uchepos*.

**Yucatán.** Mexico's southeastern frontier, the Yucatán peninsula, is home to the ancient Maya civilization, whose pre-Hispanic traditions can still be found in dishes such as *papadzules*, the "food of the lords." These enchiladas, made entirely of native ingredients, require the freshest possible tortillas, to avoid the need for frying with pork fat. They are stuffed with chopped hard-boiled eggs in place of cheese, then covered in two sauces: a green *pipián* made of pumpkin seeds and a tomato sauce lightly flavored with habanero chilies. Yet the Maya have also adapted to the latest trends of globalization with the *queso relleño*, a large Dutch cheese, imported duty-free at the port of Chetumal, and stuffed with *picadillo* (chopped meat filling).

**Northern cuisine.** The Mexican foods best known in the United States, wheat flour tortillas and beef fajitas,

Tzotzol Maya prepare tortillas at dawn at Joigelito, Chiapas, Mexico. © DANNY LEHMAN/CORBIS.

exemplify the cuisine of northern Mexico. Wheat tortillas represent a mestizo adaptation of Native American cooking techniques to the European grain in areas where expensive milling and baking facilities were unavailable. The finest wheat tortillas are from the Sonoran desert, where settlers learned to roll them into paper-thin, eighteen-inch rounds. Fajitas illustrate how working-class Mexican Americans took an inexpensive yet flavorful cut of meat, the flank steak or diaphragm muscle, then tenderized and cooked it in thin strips. Restaurateurs devised the sizzling iron plate as a fancy way of presenting an ordinary taco—bits of meat rolled up in a soft tortilla—although Mexicans generally eat corn rather than wheat tortillas. Another Tex-Mex food, chili con carne, was the simplest of moles: just beef, chili powder, oregano, and cumin. The addition of beans to chili probably began with Anglos, because it violates Mexican ideas about the proper sequence of a meal.

### Daily Bread and Tortillas

The foods eaten daily by rich and poor Mexicans differ significantly, but there is nevertheless a common structure to their meals. Work in the fields governs the eating habits of campesinos (rural laborers), who generally take two meals, a small breakfast before men set off in the morning, and a more substantial dinner when they return in the evening. To have fresh tortillas ready for breakfast, women traditionally had to awaken several hours earlier to grind corn on a basalt metate (concave grindstone) and pat it out by hand into thin disks. Because tortillas grew hard and stale after a few hours, they had to be cooked on a *comal* (earthenware griddle) before

each meal; the *nixtamal* (dough) likewise kept poorly, so the laborious grinding had to be repeated each day. One of the most significant social changes in Mexican history came in the first half of the twentieth century with the spread of mechanical mills capable of grinding the moist *nixtamal*. Freed from this onerous daily burden, women had the time to engage in commerce and craft production and thus begin to challenge the male domination of society.

In contrast to the austerity of the working class, wealthy Mexicans traditionally ate large amounts of food. The day began with *desayuno*, a simple breakfast consisting of a bread roll and coffee or hot chocolate, followed in midmorning by a substantial brunch, *almuerzo*, consisting of perhaps *mole poblano* or an omelette. The main meal, *comida*, began about two o'clock in the afternoon and progressed through an invariable sequence of four courses: a wet soup such as chicken broth, a dry soup of either rice or spaghetti, a main plate of roasted or stewed meat, and then beans. The elite accompanied their meals with imported wine, while members of the middle class drank the native pulque in the nineteenth century, and more recently beer. After awakening from an afternoon siesta, Mexicans took a *merienda* or snack of sweets, then returned to work for several hours. The *cena* or supper was taken quite late at night, often in cafés, with street foods such as enchiladas or tacos.

Class and ethnic distinctions were manifested less in the foods themselves than in their place within the daily routine. Native Americans in Oaxaca and elsewhere introduced European foods at the periphery, for example, by eating wheat bread for breakfast, while retaining the

Sor Juana, otherwise known as Juana Inés de la Cruz, was not only the most intellectual woman in 17th-century Mexico, she compiled the oldest surviving Mexican cookbook on confectionery. Consisting of 36 recipes, it is today a foundation text for the study of cloister cookery in the New World. PORTRAIT COURTESY OF THE PHILADELPHIA MUSEUM OF ART/CORBIS.

indigenous staples corn, beans, and chilies for their main daily meal. By the same token, the Hispanic elite consumed European foods for the central *comida*, and sampled lower-class foods of indigenous origin during the evening *cena*. Indeed, “slumming” at an all-night taco stand is still a favorite diversion of stylish Mexico City youth. The recent spread of an American-style workday, without the lengthy afternoon *comida* and siesta, has caused considerable loss of business for many upscale restaurants. Nevertheless, the traditional eating habits are preserved in numerous festivals throughout the year.

### Celebrating Saints and Feeding the Dead

The festival foods of Mexico are as extravagant as the campesino diet is meager. Pre-Hispanic calendars contained numerous feasts dedicated to indigenous deities, which were replaced by Catholic holy days after the Spanish arrived. Each native community adopted a patron saint, and the inhabitants dedicated their meager savings to celebrating the saint’s day with lavish abandon. Women worked for days with little rest to feed the entire community with dishes such as mole, tamales, and chocolate. These same elaborate foods were also prepared

for family ceremonies including weddings, christenings, and funerals. The wealthy Hispanic society also feasted on such occasions, although their foods tended to feature more imported goods from Europe. In recent years, traditional festival foods have even replaced French cuisine in the most fashionable restaurants.

The primary feasts of the Christian calendar—Christmas, Easter, and All Saints’ Day—are celebrated throughout Mexico. The traditional Hispanic Christmas Eve feast includes an elaborate salad of lettuce, fruit, nuts, and beets, followed by *bacalao a la vizcaína* (Biscay-style cod), made with tomato, olive oil, olives, and capers, and served with wheat bread and wine. Indigenous and mestizo families celebrate the Nativity with tamales and mole instead of imported luxuries. Good Friday features fish, lentils, *romeritos* (dried shrimp fritters with greens) and *capirotada* (bread pudding). All Saints’ Day is stretched out over three evenings, from 31 October to 2 November, known as the Days of the Dead. Families decorate the tombs of deceased relatives and construct altars incorporating salt, water, candy skulls, and *pan de muerto* (bread of the dead), decorated with strips of dough resembling human bones.

The most important civic holiday, Independence Day, celebrated on the eve of 16 September has no definite culinary traditions. There are many tricolor dishes, most notably *chiles en nogada*, stuffed green chilies with white walnut sauce and red pomegranate seeds. Nevertheless, the essence of the holiday is the *grito* or cry of independence repeated by public officials in plazas throughout the country, which lends itself not to elaborate cookery but to simple street foods: tacos, fritters, beer, and tequila.

Traditional festival foods have provided the basis for the latest trend, *la nueva cocina mexicana*, which combines Native American ingredients with the techniques of international haute cuisine. This “new Mexican cuisine” actually began in the 1950s, with dishes such as corn fungus *cuitlacoche* served in crêpes with bechamel sauce, invented by Jaime Saldívar to make a lower-class indigenous food acceptable for elite tables. By the 1990s hybrid dishes like *huauhzontle* pesto, pistachio mole, and *cuitlacoche* mousse had become ubiquitous on menus, and no fashionable Mexico City restaurant could avoid offering some version of the rose petal sauce invented by Laura Esquivel for her best-selling novel, *Like Water for Chocolate*. Many of these restaurants were owned by women, who thereby rejected the male dominance of Mexico’s traditional society. Meanwhile, in the town of Tequila (Jalisco), firms such as Sauza and José Cuervo had improved their distilling technology to a level equal with that of the finest Scotch whisky and French cognac.

The *nueva cocina* represents simply another example of Mexico’s ongoing gastronomic blending. Ever since the Spanish Conquest, cooks have combined native and European ingredients and techniques to create a sophisticated and original cuisine. It was only after the revolu-

tion of 1910 that Mexicans embraced their mestizo heritage, including the indigenous foods made of corn. The acceptance of diverse regional culinary dialects came, moreover, just as many rural cooking traditions began to be lost because of migration to urban areas and the arrival of mass-produced foods from the United States. Despite the spread of soft drinks and snack crackers, the elaborate tamales and moles prepared to celebrate festivals remain a vital source of identity within families, communities, and the Mexican nation.

**MEXICO AND CENTRAL AMERICA, PRE-COLUMBIAN.** When the Spanish conquistador Hernán Cortés set foot on the beach in the Mexican state of Veracruz, he encountered advanced cultures whose ex-

istence had not been previously suspected. The great Aztec empire, ruled by a people called the Mexica, had conquered much of the region, establishing a city of grand temples and causeways called Tenochtitlán, while the rainforest cities of the Maya were slowly returning to the jungle after being abandoned several centuries earlier. Cultures including the Totonac, Tlaxcalans, and Zapotec also met the Spanish at this time, some as friends, others as enemies. All, however, impressed many of the Spanish with their cities, governments, markets, and material goods that rivaled those of the Old World. The food and cuisine of these cultures of present-day Mexico and Central America, an area termed by anthropologists and archaeologists as Mesoamerica, are the subject of discussion here.

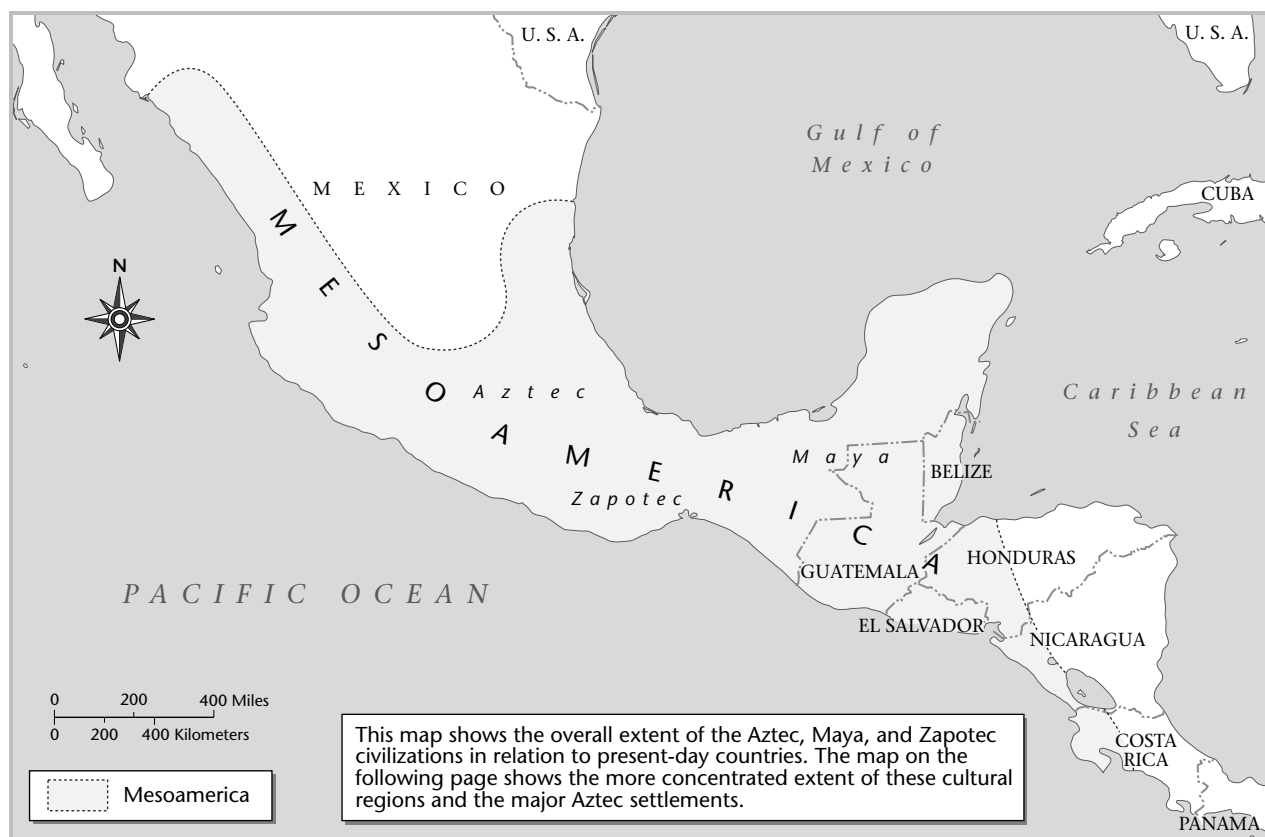

While these cultures lived in different areas, had different forms of social and political organization, and spoke a variety of languages, there were certain shared traits, including an intricate calendrical system, hieroglyphic writing, and a distinct architectural style. These cultures all made use of corn, beans, squash, chili peppers, chocolate, and domesticated dogs and turkeys. Despite some differences in preparation and availability of ingredients, many of the dishes and their style of preparation in these varied cultures were very similar.

#### Evidence for Pre-Columbian Cuisine

How do we know what and how ancient people ate? Fortunately Mesoamerica provides several lines of evidence. The documents written by the early Spanish conquistadors offer invaluable insight into the customs of early Mesoamerican civilizations. Many priests and nobility accompanied the explorations of Columbus and Cortés and learned and recorded the language, customs, and beliefs of the indigenous cultures. These documents reveal methods and techniques of food preparation, farming techniques, and available ingredients.

Archaeology provides a second line of evidence for reconstructing the foodways of these cultures. Whereas the colonial documents record what the Spanish witnessed or were told by their informants, archaeology, and the subdisciplines of paleoethnobotany and zooarchaeology, provide material evidence invisible in the ethnohistoric record. The Spanish did not often take note of foods eaten by the commoners, and without modern scientific nomenclature, it is sometimes difficult to determine exactly what plant or animal the Spanish were talking about. Archaeology often helps to clarify these problems.

The translation and interpretation of the writing and iconography of codices, the term for pre-Columbian and early Colonial books, pottery, and other works of private and public art, also provide evidence for pre-Columbian food use. Decipherment of Mayan hieroglyphs on ceramic vessels, for example, gives new insight into their use, and lists of tribute items demanded by the Mexica of their dependents show us what food items were kept in their central storehouses.

## Grains

All cultures utilize a staple food around which the rest of their cuisine is based; in Europe and the Middle East it is wheat, and in the Far East, rice. In Mesoamerica, the staple undoubtedly was corn, or maize (*Zea mays*). And not only was maize the primary foodstuff, forming the basis of virtually all meals, it had spiritual and religious significance as well. From birth, when the umbilical cord would be cut over a maize cob, to death, when a small piece of maize dough was placed in the mouth of the deceased, maize played a central role in the cultures of Mesoamerica. According to the *Popol Vuh*, the “bible” of the Maya, humans are not made of earth but rather were formed from maize dough.

Maize was prepared in a variety of ways, depending on the time of year, the race of maize, and the particular meal. For the most part, however, maize was prepared by a process called nixtamalization. The ripe maize grains were first soaked and then boiled in water mixed with burned and ground limestone or ash. After boiling, the maize kernels were ground to varying degrees on a *metate*, a flat grinding stone, and this resulting dough was used in all manner of preparations. The boiling in lime or ash makes the maize easier to grind, as well as creating a chemical reaction that makes it much more nutritious. Combined with beans, another important Mesoamerican crop, nixtamalization provided an almost complete nutritional package.

Once processed, maize was prepared either as a solid breadstuff or as a beverage. The term “beverage” is helpful for describing certain dishes, but these preparations could easily be called a gruel, porridge, or even a stew, especially with the addition of different foods. Maize dough was also soured by being stored in containers or wrapped in leaves used just for that purpose, much like sourdough bread.

*Atolli* is the Nahuatl term for a beverage made from the most finely ground maize dough mixed with water. Whole maize kernels, beans, chili pepper, marigold leaves, toasted squash seeds, and even boiled and mashed root crops, especially sweet potato, were stirred into the beverage, creating more of a stew or soup. Honey or, in the Mexica and Zapotec areas, maguey syrup, could be added for sweetness. Elite and commoner alike consumed *atolli*, although the finest, bone-white maize was reserved for the nobility, as was the addition of cacao seeds. It was generally drunk in the mornings, although it could complement a meal at any time of day.

Tortillas and tamales formed the basis of the solid breadstuffs. Tortillas are cakes of maize dough flattened to varying degrees of thickness and cooked on a ceramic griddle called a *comal*, on a hot stone, or simply over the hot ashes of a fire. *Comales* are frequently found in archaeological deposits throughout central Mexico, attesting to the importance of the tortilla in the daily diet, and

Spanish documents mention that many women were brought along on long journeys or during warfare to grind corn and prepare tortillas. Tortillas were generally paired with a sauce or casserole of spices, herbs, and vegetables and served both as food and as a utensil to transport the food to the mouth. There were different grades of tortillas, from paper-thin, pure white tortillas enjoyed by the elite, to thick and heavy tortillas for everyday consumption or for long journeys.

The presence of the tortilla among the Maya is less definite. We find few *comales* in the Mayan area, leading some to suggest that the tortilla was less important and tamales more prevalent. Tamales are thick maize dough, mixed with a vast array of foods—beans, chilis, eggs, meat, fish, and mushrooms were all incorporated into tamale dough—wrapped in leaves or corn husks, and steamed or baked in a fire. Mayan iconography also shows plates with round balls that resemble tamales, rather than flat cakes indicative of tortillas.

A fermented beverage called *balché* was made from maize and flavored with different fruits and spices. Fermented beverages were quite common in the New World (except for areas north of Mexico), and quite intoxicating as well. The Maya drank *balché* for the most part, whereas the drink in the more arid regions was called pulque and was fermented from the sap of the maguey,

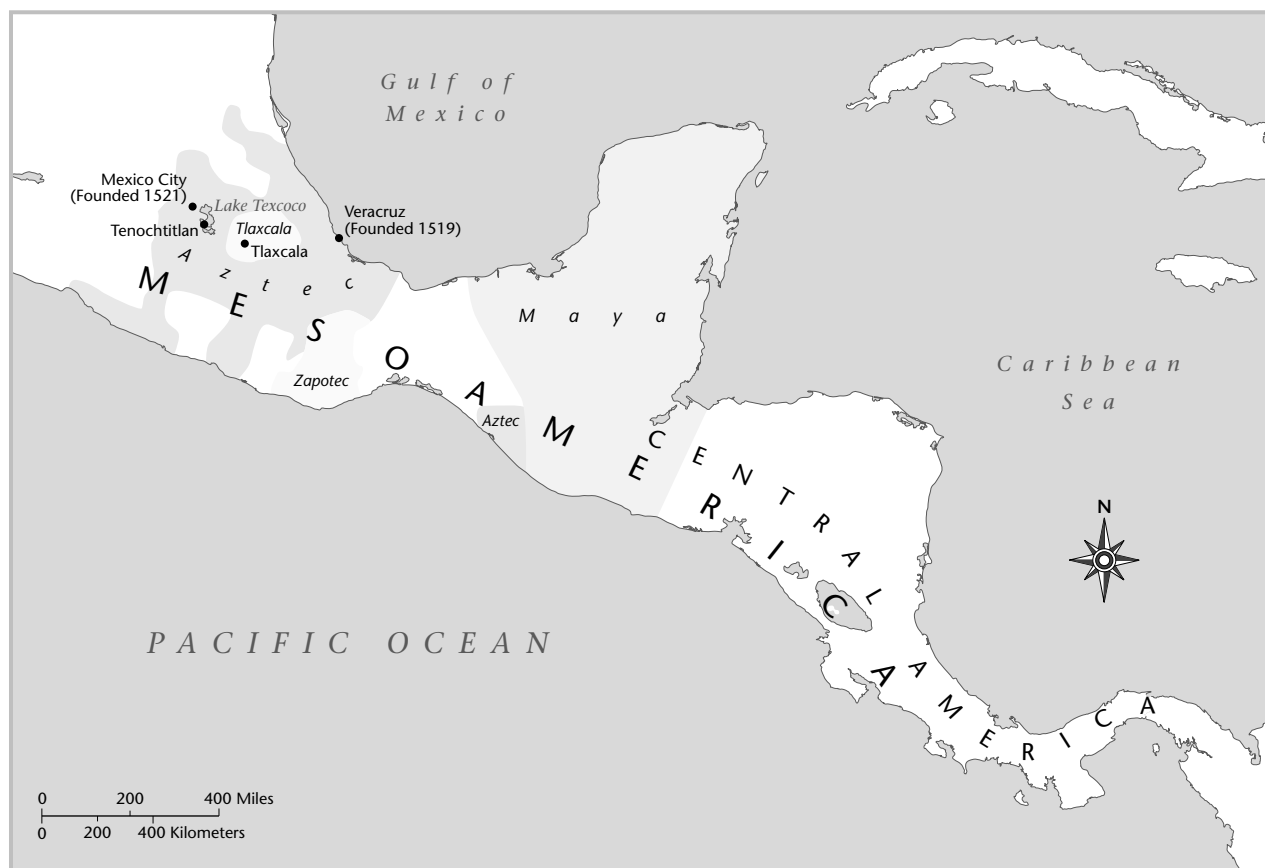

And then the yellow corn and white corn were ground, and Xmucane did the grinding nine times. Food was used, along with the water she rinsed her hands with, for the creation of grease; it became human fat when it was worked by the Bearer, Begetter, Sovereign Plumed Serpent, as they are called.

After that, they put it into words:  
the making, the modeling of our first mother-  
father,  
with yellow corn, white corn alone for the flesh,  
food alone for the human legs and arms,  
for our first father, the four human works.

From Tedlock, *Popol Vuh*, p. 140

or agave. These fermented beverages were mostly used for rituals, and public drunkenness was especially frowned upon in the Aztec empire, being punishable by death.

Maize was not the only grain utilized by Mesoamerican cultures. Amaranth, a seed crop of the genus

*Amaranthus*, was brought under cultivation throughout central Mexico and was one of the four primary tribute items demanded by the Mexica along with maize, beans, and *chia*, a relative of sage. Called *buautili* in Nahuatl, amaranth was prepared in a similar manner to maize, ground into flour for tortillas, tamales, and *atolli*. Amaranth was also popped like popcorn and ground into a lighter flour, or incorporated into regular maize dough. It was prized as a gourmet food, and the nobility enjoyed specially prepared tamales and tortillas of amaranth, as well as a sauce from the highly nutritious greens.

But the most important use of amaranth was in religious rituals. Popped amaranth flour tamales and a mixture of popped amaranth and sweet maguey syrup, called *tzoali*, were offered to certain deities. The contemporary descendents of *tzoali* are the Mexican treats *alegrías*, popped amaranth bound with molasses, which can be found throughout Mexico City. Of special importance to the Mexica were the seeds of bright red amaranth, whose color resembled blood, the most sacred of human substances. This special ritual role of amaranth, and the desire of the Spanish to eliminate any evidence of indigenous religion, may have led to its sudden disappearance from the modern diet.

### Vegetables and Fruits

The staple foods of maize and amaranth were supplemented in the daily diet by a diverse array of vegetables and fruits. Beans, although not technically a vegetable, were perhaps the most extensively cultivated crop outside of maize and amaranth. The New World beans all belong to the same genus, *Phaseolus*, and are represented by the modern-day varieties navy, wax, lima, pinto, kidney, and black, although many more were cultivated in pre-Columbian times.

Beans were not harvested green but were picked and stored dry. They were prepared generally by boiling, often with the addition of epazote, a flavorful herb that is said to reduce gassiness. The boiled beans were mashed and added to maize dough for tortillas or tamales, or made into a stew. Quite often, however, they were simply boiled in plain water, flavored with a little chili, and scooped into the mouth with tortillas.

Different types of squashes (*Lagenaria* and *Cucurbita* spp.) complemented the Mesoamerican diet in a number of ways. The cleaned and dried shells were often used as serving vessels and eating utensils. Toasted and ground, their seeds were added to tamales and tortillas, used as a flavoring for various sauces, used as a relish, or even mixed with ground beans to make a drink. The flesh was used to a lesser extent, often roasted or stewed in honey. And as is the fashion with many Mesoamerican crops, all parts of the plant were used, with the flower blossoms added to soups and stews and the greens used as wrappings for tamales or meat dishes.

A great many other vegetables were utilized by Mesoamerican cultures, including tomatoes, tomatillos, many types of greens, and a variety of root crops, such as sweet potato, manioc, and jicama. These were all commonly used in the sauces and casseroles that formed the primary part of a meal along with tortillas and tamales. Root crops have been the subject of debate in Mesoamerican archaeology. Some see their role in the diet as relatively minor, whereas others stress their importance beyond what is indicated in the ethnohistoric record. Little mention is made of them by the Spanish, yet records of explorations in the Mayan area mention large fields of root crops, interspersed with other cultigens.

Although technically a fruit, avocado (*Persea americana*) generally played the role of a vegetable. It could be eaten simply sliced and wrapped in a tortilla, added to soups, or prepared as a relish, similar to guacamole. Also eaten were the cactus pads and fruits of a variety of cactus, primarily *Opuntia* sp., as well as different parts of the succulent agave (*Agave* sp.), also known as maguey. Fruits, and especially fruit trees, play a major role in Mesoamerican cuisine, although their methods of preparation were fairly simple. Commonly known and frequently used New World cultigens include pineapple, papaya, and passion fruit, while lesser-known fruits such as chico zapote (*Manilkara zapota*), the various species of *Annona* including soursop and cherimoya, and hog plum (*Spondias mombin*) were also eaten. When not eaten plain, fruits were often made into intoxicating beverages used in ceremonies and rituals. The fruit tree orchards held special significance to the Maya, and when the Spanish forced

them to cut them down, in large part because of the excessive drinking and intoxication from fruit beers, the Maya were devastated. Orchards were not simply locations for harvesting fruit, but were sacred sites passed down and maintained through generations.

### Spices, Herbs, and Specialty Items

Fundamental to Mesoamerican cuisines is the chili pepper (*Capsicum* sp.) perhaps second in importance only to maize. It acquired the name “pepper” as it was the closest to black pepper (*Piper nigrum*) that Columbus could find in the New World, although it is not very similar at all. However, as an all-purpose spice to flavor nearly all concoctions, it fulfilled the role of black pepper quite well. It was sprinkled over sauces, ground into maize dough, and boiled with beans, providing taste as well as great quantities of vitamins A and C. Its importance is evident in the ritual fasting of the Aztec priests, who considered a “fast” an abstinence from salt and chili, as well as meat.

Chilies were also used in nonculinary fashion. Children were punished by being held over chili smoke, and during warfare, calabashes (squash shells) with coals and chilies were thrown at the enemy to create a pungent smoke.

No discussion of Mesoamerican cuisine can proceed without mentioning chocolate, or cacao (*Theobroma cacao*). Primarily used by the elite, cacao was prepared as a beverage and was served as the last course of a meal. Cacao beans were prepared by being fermented, cured, roasted, and then ground into a powder, which was added to hot water and frothed. The Aztec would create a foamy head to the drink by using a spoon or a special utensil, whereas we see from some Mayan iconography that they would pour the cacao from one vessel to another to make the foam. Creating this foam was integral to the preparation of cacao, and to be served a drink without it was a grave insult.

An innumerable array of additions flavored these cacao drinks. Honey or maguey syrup was added for sweetness, maize dough could be added to thicken the drink, and herbs, spices, and flowers provided different tastes and flavors. The Aztec and Maya frequently mixed in vanilla, the seedpod of an orchid grown on the Gulf Coast, and achiote (*Bixa orellana*), although the latter was more to impart a deep red color than for taste. Achiote, the seed of a small tree, was actually used to tint many things, including human skin.

Countless flowers also flavored cacao drinks. Marigold (*Tagetes lucida*), *Cymbopetalum penduliflorum*, and *Quararibea funebris* were all added to the cacao drink, each flower providing a different taste, ranging from cinnamon to black pepper to ripe melon. Some flowers were added to the finished beverage, whereas others were closed in a sealed container with the dried beans to impart their aroma.

Cacao was reserved solely for the elite, and generally only the males. At the great Aztec banquets, the men were served vessels of cacao at the completion of the meal, whereas the women drank a beverage of chia seeds and chili. Priests also likely drank cacao, as it was often mixed with hallucinogenic substances such as psychoactive mushrooms or peyote.

Cacao also served as a form of currency. The beans were used as a coin, and there were those who would attempt counterfeiting by filling empty cacao shells with clay, although this was a heavily punishable offense. The use of cacao as currency continued up to the twentieth century in parts of Mesoamerica.

### Meat and Fish

When the Spanish arrived, they likened the diet of the inhabitants of Mesoamerica to a perpetual Lent, so little was their meat consumption. Prehistoric environmental factors left Mesoamerica with few large mammals. Among the few animals raised in Mesoamerica were the dog, the turkey (*Meleagris gallopavo*), and the Muscovy duck (*Cairina moschata*). One could also include among the domesticated animals several types of stingless honeybee and the cochineal insect, the latter used for a red dye later employed by the British for their “redcoats.”

The meat of these domesticated animals was reserved for special feasts, with the exception of the nobility, who enjoyed meat on a daily basis. For any one of these feasts, a huge quantity of dogs, turkeys, and duck would be fattened and slaughtered and prepared generally in tamales or in one of the many soups and stews. Turkeys were considered a feast food, with the Maya especially reserving this bird for ceremonies related to planting and rain. After the introduction of the chicken, the role of the turkey diminished, although it was still used in the most important rituals.

At the time of European contact there were many dog breeds, including a rather large, hairless breed that has since become extinct. These breeds were separate from the dogs used as guard dogs, for hunting, or for companionship. The raising of edible breeds was a lucrative profession, and the animals were fed a rich diet of maize and even large quantities of avocado.

The New World was replete with wild game, however, and these were hunted and even somewhat “tamed.” Several types of deer, while technically “wild,” were kept in pens nearby the living quarters, and it was even said that Mayan women would suckle baby deer from their own breasts. Deer was probably the most commonly hunted and eaten of the wild animals; it has been found in archaeological contexts from the highest nobility to the lowest of peasants. Also utilized were two types of iguana, whose eggs and flesh were eaten, the armadillo, the peccary, the tapir, and several types of monkeys.

Food from the sea was important as well. Tropical fish, lobsters, other shellfish, and manatees were all

caught and transported great distances to the major Aztec, Mayan, and Zapotec cities to be enjoyed by nobility and commoner alike. The fish were usually sun-dried or salt-dried, using the resources from the massive saltworks along the coastal regions.

From freshwater lakes and streams came turtles, crocodile, and many types of fish. The Aztec, who lived by Lake Texcoco, made perhaps the most extensive use of their lake resources, extracting a variety of fish, shrimp, insects, and insect eggs. A type of water bug called *axay-acatl* was collected, formed into balls, and cooked in maize husks, and the eggs of this same water bug, called *ahuau-til*, were eaten in tortillas and tamales. A tiny worm that lives in the lake was gathered and cooked with salt and chili until black and soft, and a type of algae was skimmed off the top of the lake, formed into bricks, and left in the sun until it turned black, when it was utilized somewhat like cheese. The Aztec were not the only ones to indulge in insects. The Maya and the Zapotec prepared and ate many insects, which apparently disgusted the Spanish, but little is known of how they were prepared.

The contact between Europe and the New World fundamentally changed the cuisines of the world. Where would Italian cuisine be without the tomato; Indian cuisine without the chili pepper; or the cuisines of northern Europe without the potato? Some of the ingredients and dishes presented here are instantly recognizable, whereas others are not, but this far from comprehensive list gives only an idea of the wealth and complexity of the pre-Columbian cuisines of Mesoamerica.

**MICROBIOLOGY.** Microbiology is the study of a diverse group of microscopic organisms, or microorganisms: bacteria, fungi, algae, protozoa, and viruses. Bacteria are prokaryotes; the other microorganisms are eukaryotes. Prokaryote cells lack a nuclear membrane and membrane-bound organelles. Recently, bacteria have been divided into eubacteria and archaebacteria, with the latter more closely related to eukaryote cells. Bacteria are mostly unicellular and range in size from tiny mycoplasmas, 200 nanometers (that is, 200 billionths of a meter, or less than 1/100,000 of an inch) in diameter, to the recently discovered *Thiomargarita namibiensis*, at one millimeter (or about 1/25 of an inch). *E. coli* cells are one to two micrometers in length (about five to ten times the diameter of the mycoplasmas). Fungi include yeasts, molds, and mushrooms. The bread, wine, and beer yeast, *Saccharomyces cerevisiae*, is ten micrometers (about 1/2,500 of an inch) in diameter. Algae are photosynthetic organisms, unicellular or multicellular. Protozoa are microscopic, unicellular, and usually motile. Viruses are not cellular organisms; they are intracellular parasites of animals, plants, or bacteria. They are composed of nucleic acid (DNA or RNA) enclosed in a protein coat. Viruses range from 18 to 450 nanometers (from less than one-millionth to almost 1/50,000 of an inch). Microorganisms, with the exception of viruses, can be observed with a compound light microscope (up to  $\times 1,000$  magnification). Electron microscopes (up to  $\times 100,000$  magnification) are used to visualize viruses.

#### History of Microbiology before Pasteur

Microorganisms were first visualized by Antoni van Leeuwenhoek (1632–1723), a Dutch cloth merchant and an expert lens grinder. His simple microscopes magnified up to three hundred diameters. In the eighteenth century, many people still believed that living organisms could arise spontaneously from organic matter—the doctrine of abiogenesis, or spontaneous generation.

Lazzaro Spallanzani (1729–1799), an Italian priest and physiologist, did an experiment that came close to proving that life (in this case, microorganisms) does not arise spontaneously from nonliving matter. He sealed flasks containing broth and then boiled them. No spontaneous generation or growth occurred in the flasks; how-

ever, the debate continued, as proponents of the doctrine said that air was needed for spontaneous generation. Opponents of this doctrine had a very difficult task trying to prove a negative, namely that something did not happen.

The ancient Egyptians and Romans were comfortable with the idea that organisms invisible to the naked eye could cause disease. During the Dark Ages and the medieval period of Western history, this idea virtually disappeared. In the sixteenth century, Girolamo Fracastoro (1483–1553) described disease passing from one person to another by “germs.” Athanasius Kircher (1602–1680) furthered the “germ theory” by observing bacteria from plague victims.

### History from Pasteur Onward

Louis Pasteur (1822–1895) was an intellectual giant who dominated science in the middle of the nineteenth century. In 1861, in the midst of a twenty-year study of microbial fermentation, Pasteur dealt the deathblow to the doctrine of spontaneous generation by demonstrating the presence of microorganisms in the air and then by showing that sterile liquid in a swan-necked flask remained sterile. Air could enter such a flask, but microorganisms could not. In 1875, Ferdinand Cohn (1828–1898) published the first classification of bacteria, and used the genus name, *Bacillus*, for a spore-forming bacterium. In 1875, Robert Koch (1843–1910), a German bacteriologist, proved that a spore-forming bacterium, *Bacillus anthracis*, caused anthrax. His experiments demonstrated four principles, now known as Koch’s postulates, which are still the hallmark of disease etiology: (1) the microorganism must be present in every diseased animal studied, but not be isolated from healthy animals; (2) the microorganism must be isolated from the animal and cultivated; (3) an animal inoculated with the microorganism must develop the disease; (4) the same microorganism must be isolated from the diseased animal inoculated with the microorganism. Working independently on anthrax, Pasteur and his colleagues confirmed Koch’s findings. Koch introduced three practices that allowed bacteriologists to obtain pure cultures simply: (1) a semisolid medium composed of nutrients solidified with gelatin, (2) platinum needles sterilized in a flame to pick up bacteria, (3) streaking of bacteria onto a gelatin surface to obtain single cells that would grow into colonies. In 1881, Fanny Hesse, the wife of German bacteriologist, Walther Hesse, suggested using a seaweed extract, agar, which she used to thicken jam, to solidify media in petri plates. Agar had neither of the disadvantages of gelatin: it was rarely degraded by microorganisms and it stayed solid at temperatures above 28°C (about 82°F). Agar is still the solidifying agent of choice. In 1882, Koch used the pure-culture techniques to isolate the bacterium that causes tuberculosis. In 1884, Charles Chamberland, a collaborator of Pasteur’s, developed a porcelain filter that would retain all bacteria. When, in 1892, a young Russian scientist, Dmitri Iwanowski, transmitted tobacco mo-

### YEAST EXTRACT

In the United Kingdom, South Africa, and Down Under, people enjoy yeast spreads—that is, spreads made from a dark-brown, extremely salty yeast extract. Oddly enough, one, Marmite, is preferred in Australia, and another, Vegemite, is preferred in New Zealand. Some say Marmite is sweeter than Vegemite; others say that Marmite has more caramel flavor. One of babies’ first foods Down Under is toast fingers spread with Vegemite or Marmite. These spreads are rich in niacin, thiamine, and riboflavin. Neither of these spreads is tolerated well by North Americans.

saic disease to healthy plants using a porcelain-filtered extract, he postulated the presence of a toxin. In 1898, the Dutch microbiologist, Martinus Beijerinck, reproduced Iwanowski’s results, but he postulated the existence of very small infectious agents, “filterable viruses.” Thus began the field of virology, although visualization of viruses had to wait until the development of the electron microscope in the 1930s. Medical bacteriology progressed rapidly at the Pasteur Institute in Paris, where Pasteur presided, and the Koch Institute in Berlin, where Koch presided.

### History of Food Preservation Microbiology

In 1810, Nicolas Appert (1750–1841) applied Spallanzani’s results to develop a system of preserving food by sealing it in airtight cans and heating the cans. Without understanding that the heat treatment, or “appertization,” was killing microorganisms in the canned food, Appert established the basis for the modern practice of canning. In 1852, Napoleon III asked Pasteur to study the problem of “wine diseases,” particularly wine souring. In 1886, Pasteur proclaimed that the off-flavors in wine were caused by contaminating microorganisms. He suggested heating (pasteurizing) the grape juice to kill the spoilage bacteria. He discovered that some microorganisms could grow in the absence of oxygen. He used the term “anaerobic” to apply to microbial metabolism that occurs only in the absence of oxygen, and “aerobic” for metabolism that occurs under normal atmospheric conditions. Fermentation of grape juice by yeast is one kind of anaerobic metabolism. He also described the anaerobic degradation of protein, or putrefaction, by bacteria. Aerobic bacteria, namely the acetic-acid bacteria, were the cause of wine souring. Some of these bacteria metabolize ethanol to acetic acid; others metabolize the acetic acid to carbon dioxide and water. The process of pasteurization, a mild heat treatment of liquids, originated as a means of preserving the

## BACTERIA AS FOOD

In the pre-European Aztec culture, people harvested the cyanobacterium, *Spirulina*, from lakes for food, and still do so in Chad. Cyanobacteria are capable of photosynthesis, and so some lakes in Chad and in Mexico develop a deep green color. *Spirulina* may be the only bacterium directly consumed by people. Today, about nine hundred tons a year of *Spirulina* is produced, mainly by the United States and Thailand. The spirulina product is 65 percent protein and amino acids, 20 percent carbohydrates, and 5 percent fats. *Spirulina* is rich in vitamins A, D, K, and B<sub>12</sub>, as well as beta carotene.

desired flavor of milk, fruit juices, beer, and wine. For example, Pasteur recommended that heating bottled wine for a short time at 122°F (50°C) would kill the lactic-acid and acetic-acid bacteria that can spoil wine. In traditional pasteurization, liquids are heated at about 145°F (63°C) for thirty minutes, then held at 50°F (10°C). Nowadays, flash or high-temperature, short-time (HTST) pasteurization is the preferred method (about 162°F [72°C] for fifteen seconds, followed by rapid cooling to 50°F [10°C]) because it has less effect on the flavor of the food being heated. Currently, milk is pasteurized to eliminate the bacteria responsible for tuberculosis, food poisoning, undulant fever, and Q fever. The treatment does not result in sterilization of milk, which can contain twenty thousand bacteria, such as lactobacilli, per ml post-pasteurization. More common in Europe than other parts of the world, is ultrahigh temperature (UHT) treatment (300°F [148.9°C] for one to two seconds), which sterilizes milk, allowing it to be stored without refrigeration for more than the limit of two to three weeks for pasteurized milk. Many brewing companies pasteurize their bottled or canned beer at 140°F (60°C) for a few minutes. Pasteurization is infrequently used, however, in modern wine-making, as it adversely affects the flavor.

Cohn and John Tyndall (1829–1893) both demonstrated that the endospores of *Bacillus subtilis* cells were far more resistant to heating than were vegetative bacteria. Tyndall developed a method of sterilizing liquids that contained bacterial spores: a medium was first incubated to allow the spores to germinate, then heated to kill most of the bacteria. This process, later termed “tyndallization,” was repeated several times. This was a very important development in food science since the bacteria that form endospores include the food-borne pathogens, *Clostridium botulinum*, *C. perfringens* and *C. difficile*. Today, canned food is subjected to a temperature–time

treatment that ensures the death of heat-resistant bacterial endospores, particularly those of *C. botulinum*.

For hundreds of years, substances that inhibit microbial growth have been added to foods in an attempt to prevent spoilage. One of the oldest practices is the salting of meat and fish as a means of preservation. Growth of most bacteria is inhibited by the high osmotic strength generated by the salt. In a relatively dry climate, salted meat can last up to twelve months. In 1958, the United States government determined that no chemical could be added to food or beverages without having been tested for safety. Three important antifungal preservatives for acidic foods (foods with a pH of 4.6 or less) such as canned drinks, salad dressings, cheese, and wines, are benzoic acid, sorbic acid, and propionic acid (or their salts). Sodium nitrate has been used in meat in China and the Middle East since 1200 B.C.E. A bacterial conversion of nitrate to nitrite results in a reaction with the heme pigment, giving the pink color of ham. Nitrite is antibacterial and prevents the germination of *C. botulinum* and other anaerobic bacteria in meats like ham, bacon, and frankfurters. Sulfur dioxide in some form, for example as produced by sodium metabisulfite, is used to control yeast and bacteria in wines and bacteria in brewing. Sulfur dioxide or bisulfite is an unusual chemical in that it is also an extremely effective antioxidant. Fermentation is another method of preservation. A commonly held dictum is that pathogenic bacteria do not grow at pH levels below 4.5. Fermented foods are inoculated with microorganisms, which reduce the pH of the food by producing acid during their growth. Acids such as acetic or citric acid are also added to decrease the pH of foods. Heat treatments are more effective at killing microorganisms at lower pH. It appears that low pH does not ensure safety from pathogens: in 1993, *E. coli* 0157:H7 in fresh-pressed apple juice caused an outbreak of diarrhea and hemolytic uremic syndrome. *Yersinia* spp. may also be able to survive in low pH foods.

Irradiation is a process that destroys microbial pathogens in food. Gamma rays from cobalt 60 or cesium 137, X rays (five million electron volts [5 MeV] maximum), and electrons (10 MeV maximum) are approved sources in the U.S. Irradiation was first used in the U.S. to ensure safe food for astronauts. Subsequently, the Food and Drug Administration (FDA) approved irradiation for wheat, wheat flour, and potatoes. Currently, irradiation is used mostly for spices, but also to disinfect cured meats, to kill *Trichinella spiralis* in pork, to control salmonella on chicken carcasses, and to reduce microbial load on fresh fruits and vegetables. There is some public resistance to irradiated foods, as the thought is that the food becomes radioactive. It does not.

## Control of Microorganisms in Food

The contemporary food microbiologist has the challenges of a growing number of food pathogens and food spoilage. For example, eighty percent of commercial

chickens in the U.S. are contaminated with *Campylobacter jejuni*. The food microbiologist may be involved in food manufacturing and processing, in retail food, in research in a university or government organization, such as the Agricultural Research Service of the United States Department of Agriculture (USDA), FDA, Centers for Disease Control and Prevention, and National Institutes of Health (NIH); or in food-plant inspection or the USDA's Food Safety Inspection Service (FSIS). In food plants, the food microbiologist is often a food technologist with a thorough training in chemistry as well as microbiology, who establishes a laboratory quality assurance manual (LQAM), a training program, and a statistical quality-control program. The food microbiologist must be versed in good manufacturing practices (GMP's), standard operating procedures (SOP's), sanitation, Hazard Analysis and Critical Control Points (HACCP's), rapid methods for the isolation and identification of microorganisms, as well as assays for toxins. HACCP's are designed to ensure food safety, extending beyond microbiological hazards, to chemical (for example, those from mycotoxins and pesticides) and physical (for example, from glass breakage) dangers. To generate an HACCP, the hazards in the plant's processes must be identified, the risk involved at each Critical Control Point must be established, and the critical levels of pathogens at each step in the process must be determined. The process must be monitored, and the monitoring verified. HACCP's are rapidly being required by government industries for more and more food processors. The USDA now mandates that all meat and poultry processors that are federally inspected have an HACCP in operation. The FDA now requires HACCP's for fruit-juice producers. Sanitation methods and monitoring are an extremely important part of any HACCP and a chief duty of a plant's food microbiologist. Surfaces in food-processing plants, meat carcasses, fruits, and vegetables must be kept pathogen-free. The use of simple rapid ATP detection systems (ATP—adenosine triphosphate—degrades quickly and is only found in living cells) allows a food microbiologist to involve plant workers in the sanitation effort. Workers swab sanitized surfaces, process the swab, and read the print-out that has been calibrated to tell them the level of cellular contamination. They can resanitize surfaces until the results are acceptable.

In food-production and retail-food plants and in the home, good hygiene, especially hand washing, is the most effective way to eliminate the transmission of these pathogens. Another important practice is proper refrigeration of foods. Finally, proper cooking of raw meats, fish, and eggs by the consumer will destroy any remaining pathogens.

The explosion in genetic and immunological research in the 1980s resulted in many antibody-based and DNA-based methods for the identification of bacteria and toxins. These methods are rapid, reliable, sensitive, and becoming simpler daily. The time-consuming step

in the assays is the necessity of initially growing or in some way enriching for the pathogen of interest. There are DNA-based assays for all the major food-borne pathogens. These assays use either DNA probes (usually of 16S rRNA genes, since there are relatively so many copies of these genes in cells) or PCR (a short DNA sequence is amplified in a thermocycler). There are also antibody-based assays for the major food-borne pathogens and toxins. These assays depend upon an antibody produced to some component of a bacterial cell or toxin. The most commonly used antibody-based assay is an ELISA, an enzyme-linked immunosorbent assay. It is described as a "sandwich assay." The test substance is added to a solid support to which the antibody to a particular pathogen is bound. The cell or toxin binds to the antibody. A secondary antibody, which is conjugated to an enzyme, binds to the primary antibody. Addition of the enzyme's substrate results in activity that can be detected. As the field of diagnostics speeds on, the food microbiologist must devote time to a continuing evaluation of newly emerging technologies aimed at reducing or eliminating pathogens as well as microorganisms that adversely affect the quality of food.

### Use of Microorganisms for Various Helpful Ends
